SURVEY REPORT

on

Mobile Harbor, Alabama
SUBJECT: Mobile Harbor, Alabama - 55480

DA, South Atlantic Division, Corps of Engineers, 510 Title Building, 30 Pryor Street, S.W., Atlanta, Georgia 30303 4 November 1980

TO: Board of Engineers for Rivers and Harbors, Kingman Building, Fort Belvoir, Virginia 22060

I concur in the recommendations of the District Engineer.

PLEASANT H. WEST
Colonel, Corps of Engineers
Acting Division Engineer
FOREWORD

This feasibility report presents a recommended plan and detailed alternatives for navigation improvements at Mobile Harbor, Alabama. All plans are compared based on October 1978 cost and benefit data. The cost and benefits of the recommended plan have been updated to August 1980 price levels and construction time shown as four and one-half years. This information is available in attachment 1 of the Summary Report.

Benefit and Cost Update (August 1980)
SUMMARY REPORT
MOBILE HARBOR, ALABAMA
FEASIBILITY REPORT
CHANNEL DEEPENING FOR NAVIGATION

INTRODUCTION

Dredging to provide a navigation channel in Mobile Bay and Mobile River began as a result of enactment of the River and Harbor Act of 20 May 1826 by the U.S. Congress. During the period 1826 to 1857, a channel 10 feet deep was dredged through the shoals in Mobile Bay up to the city of Mobile. Subsequently, further modifications to the channel were authorized and the original Federal project was enlarged by the addition of the Arlington, Garrows Bend, and Hollingers Island Channels within the bay, a channel into Chickasaw Creek from the Mobile River, and maintenance snagging in Three Mile Creek. The most recent main channel modification to be constructed was authorized by the River and Harbor Act of 3 September 1954 and provided a 40-foot depth and 400-foot width in Mobile Bay to the mouth of Mobile River and a 40-foot depth in Mobile River to the highway bridge, the width varying from 400 to 775 feet. The Senate Public Works Committee on 16 July 1970 and the House Public Works Committee on 15 December 1970, under provisions of Section 201 of the 1965 Flood Control Act, authorized a 40- by 400-foot channel, branching from the main ship channel and extending through a land cut to the Theodore Industrial
Theodore Ship Channel was reauthorized in the Water Resources Development Act of 1976 and construction was initiated 23 October 1972 on the barge channel extension and 9 April 1979 on the deep draft channel. Recent changes in both vessel characteristics and commodity movements indicate that modifications to the harbor are necessary to maintain efficient, safe and economical operations. Hence, this study was undertaken to determine the need and justification for modifying the existing project. The study area is shown on Plate 1.

STUDY AUTHORITY

Responding to the problems cited above and recognizing the national economic importance of deep-draft ports and their facilities, the Public Works Committee, United States House of Representatives, adopted a resolution on 24 June 1965 requesting that the Board of Engineers for Rivers and Harbors determine the advisability of modifying Mobile Harbor.

SCOPE OF THE STUDY

This study considered the need for modifications to the existing Federal project at Mobile Harbor, including the authorized improvements for the Theodore Ship Channel, to accommodate present and prospective commerce. Plans were formulated to meet both identified navigation needs as well as other water-related problems. Through a screening process, the better plans were identified and associated costs and benefits therefore were estimated. An assessment was also made of the economic, environmental and social impacts of the alternative plans. Depth and detail of the study were commensurate with the level of consideration given to the particular plan and the objective of selecting the most suitable overall plan and determining its
feasibility and acceptability. The existing Federal project, detailed alternatives and the recommended plan for improvement are shown on Plates 1 through 5.

STUDY PARTICIPANTS AND COORDINATION

The Corps of Engineers was responsible for the conduct and coordination of the study, the formulation of plans, and the preparation of this feasibility report. The study was coordinated with appropriate Federal, State and local agencies, including the U.S. Fish and Wildlife Service, Environmental Protection Agency, National Marine Fisheries Service, Alabama State Docks Department, Alabama Development Office, Alabama Coastal Area Board, Alabama Department of Conservation and Natural Resources, and the South Alabama Regional Planning Commission. The District Engineer formed the Mobile Harbor Advisory Committee. This committee represented the varied interests in the local area and offered an objective review of data and study results. In addition, public meetings were held on 25 April 1967, 22 January 1974, 12 November 1975, 22 November 1976, and on 31 July 1979 to give interested parties an opportunity to express their views and opinions regarding the proposed modifications. Additional workshop meetings were held with interested Federal and State agencies and individuals to address specific study needs and issues as they arose. Also, a technical committee was formed in June 1971 of State and Federal agencies to analyze dredging in Mobile Bay and conduct a baseline environmental study. Their final report was published in July 1973.

OTHER STUDIES

Ten reports have been prepared on Mobile Harbor. The first was printed as House Document Number 1763, 64th Congress, 2d Session. The
following reports are the most recent ones, beginning with the report that recommended the existing Federal project dimensions.

The report published as House Document Number 74, 83rd Congress, 1st Session, recommended modification of the existing project to provide a 42- by 600-foot channel about 1.5 miles long across Mobile Bar; a 40- by 400-foot channel in Mobile Bay to the mouth of Mobile River; a 40-foot channel in Mobile River to the Cochrane Bridge, varying in width from 500 to 775 feet; and several branch channels, turning basins and anchorages. The improvement was authorized by the River and Harbor Act approved 3 September 1954. The improvements were completed in 1965.

As noted earlier, studies to consider additional Federal modifications for Mobile Harbor were authorized in 1965. At the request of local interests to expedite consideration for Federal development of the Theodore Ship Channel, the Chief of Engineers authorized an interim report limited to consideration of those improvements on 6 March 1968. Pursuant to an interim report recommendation, Senate Public Works Committee on 16 July 1970 and the House Public Works Committee on 15 December 1970, under provisions of Section 201 of the 1965 Flood Control Act, authorized a 40- by 400-foot channel, branching from the main Mobile Bay Ship Channel and extending through a land cut to the Theodore Industrial Park with an anchorage area at the shoreline. During preconstruction planning for these improvements, a shoreline turning basin and a 6000-foot barge channel extension were also included in the plan for improvement. The modified plan was reauthorized by the Congress in October 1976 and construction is currently being performed.
THE REPORT AND STUDY PROCESS

This report has been arranged as a main report with five appendices. The main report is a nontechnical presentation of the feasibility study for considered modifications and includes a description of the study area; a discussion of the problems and needs; the formulation of plans for satisfying those needs; a summary of economic studies showing the benefits, costs and justification; a delineation of plan responsibilities in terms of Federal and non-Federal contributions; a summary of environmental, social and economic impacts; and recommendations for implementing the selected plan. Appendixes 1 through 4 present the Draft Environmental Impact Statement, the Section 404(b) Evaluation, the pertinent correspondence which represents the Public Views and Responses, and the Fish and Wildlife Coordination Act Report, respectively. Appendix 5 presents the technical support data for material discussed in the main report.
PROBLEM IDENTIFICATION

The problems and needs examined relate to Mobile Harbor's ability to efficiently handle the present and future deep-draft commerce of the tributary area without unacceptable adverse impacts upon the surrounding environment.

NATIONAL OBJECTIVES

The "Principles and Standards for Planning Water and Related Land Resources" requires that Federal and federally assisted water and related land planning be directed to achieve National Economic Development (NED) and Environmental Quality (EQ) as equal national objectives. NED is to be achieved by increasing the value of the nation's output of goods and services and improving national economic efficiency. EQ is to be enhanced by the management, conservation, preservation, creation, restoration, or improvement of the nation's natural and cultural resources and ecological systems.

EXISTING CONDITION (PROFILE)

The development, economy and the natural and human resources of the area comprise a profile of existing conditions without any considered Federal improvements. These profile data are discussed in the following paragraphs.

Principal Industries and Activities. The economy of the Mobile area is based on its port and port-related activities, its natural resources and their use by industry, and the growing noncommodity-producing, service-oriented industries. In 1974, an estimated 18,000, or 13 percent of the total work force of the Mobile area, were
employed by manufacturing industries closely allied with or dependent upon the port and related waterways. An additional 2,800 persons were employed in water transportation and transportation services which were directly related to port- and waterway-associated activities. A large percentage of the 3,000 employees involved in railroad, motor freight, and warehousing activities work at jobs connected with the port and waterways.

Total employment within Mobile and Baldwin Counties grew slightly during the decade from 1960 to 1970 from 121,400 to 123,100. These figures reflect the impact on the area of the phaseout of Brookley Air Force Base in the mid-1960's. In 1970 the wholesale and retail trade sector employed the greatest numbers, 25,400, closely followed by the manufacturing industries with 24,700 workers. The government was the third most important employer with 17,200 employees. The remaining industries employed 32,700 persons.

The Alabama Development Office has published data which announces investments by new and expanding industries in the Mobile area. More than $714.3 million in estimated investment was announced for the years 1973-1975, Mobile County receiving $693.6 million and Baldwin County $20.7 million. The investments indicate a greatly increased relative importance of chemicals and allied products, which account for 82 percent of the study area's projected growth.

Employment and Income. In 1974, with employment at 151,900, the unemployment rate in the study area reached 3.7 percent versus a State of Alabama rate of 4.0 percent, and a national unemployment rate of 5.6 percent.

In 1970 the study area's per capita income was $2,501. Although this represents a 30-percent increase over the 1962 figures of $1,918,
it was approximately $1,000 less than the national per capita income in that year. Based on estimated figures for 1976, the State and the study area continue to lag behind the nation for the period 1970-1976 in per capita income, but had surpassed the nation in rate of growth of income.

Transportation. A well-developed system of transportation is essential to an area's economic well-being. The study area is served by an integrated network of highway, air, rail, and water transportation facilities. The area's highway system consists of six U.S. highways, two interstate routes, and a secondary system composed of State and county roads. Commercial and private air transportation are available at the municipally owned Bates Field and Brookley Aerospace Center. The railroads providing transportation service in the area are the Illinois Central Gulf, the St. Louis-San Francisco, the Southern, and the Louisville and Nashville. The Alabama State Docks Terminal Railway connects these railroads to portside tracks, other marine terminal facilities, and industries near the Alabama State Docks.

The study area is also served by a well-developed system of waterways. Deep-draft facilities are provided by a channel extending from the entrance of the bay, northward into the Mobile River. Barge traffic in the area is accommodated by the Mobile-Tombigbee-Black Warrior system, the Mobile-Alabama-Coosa River system and the Gulf Intra-coastal Waterway which extends east-west across the southern part of the bay. The Tennessee-Tombigbee River project is now under construction and is expected to be completed in 1986. It will connect a 16,000-mile inland water system, located in 23 states, with the Gulf of Mexico at the Port of Mobile.

Port of Mobile. The first Federal project for Mobile Harbor was authorized by Congress in 1826. Since that year numerous modifications and extensions to the harbor channels have been authorized and
constructed. The completed portion of the project, authorized by the 1954 River and Harbor Act, is comprised of the following features:

- A 42- by 600-foot channel about 1.5 miles long across Mobile Bar.
- A 40- by 400-foot channel in Mobile Bay to the mouth of Mobile River.
- A 40-foot channel in Mobile River to the highway bridge, the width varying from 500 to 775 feet.
- A 25-foot channel from the highway bridge to and up Chickasaw Creek to a point 400 feet south of the mouth of Shell Bayou, the widths being 500 feet in Mobile River and 250 feet in Chickasaw Creek.
- A turning basin 40 feet deep, 2,500 feet long, and 800 to 1,000 feet wide, opposite the Alabama State Docks.
- A turning basin 40 feet deep, 1,000 feet wide, and 1,600 feet long opposite Three Mile Creek.
- A 27- by 150-foot channel from the mouth of Mobile River to and including a turning basin 250 feet wide and 800 feet long in Garrows Bend, and continuing thence to a turning basin 850 feet long and 600 feet wide opposite Brookley Field ocean terminal, thence a 27- by 150-foot channel along Arlington Pier to the Mobile Bay Channel.
- Maintenance by snagging Three Mile Creek from its intersection with the Industrial Canal to Mobile River.

Maintenance of the Federal project consists of discharging the material dredged by hydraulic pipeline dredge along both sides of the bay channel in Mobile Bay and transporting the material dredged from the entrance channel by hopper dredge to an EPA interim approved disposal area in the Gulf of Mexico. The dredged material for Mobile River is currently being placed in approved disposal areas adjacent to the river.
The Alabama State Docks operate 2 bulk terminals and 26 general cargo berths above the Bankhead and Interstate 10 Tunnels. It operates one bulk handling facility below the tunnels on McDuffie Island. With a 40-foot ship channel into Theodore, the Alabama State Docks is committed to provide a public deep-draft bulk terminal at the turning basin to accommodate the loading/unloading of liquid cargo and storage for products such as inbound crude oil, outbound petroleum products and other bulk liquids that might be shipped through the Port of Theodore by tankers. There are 10 private terminals and docks above the tunnels that handle cargo moving inbound/outbound by deep-draft vessels. The major operators of these private terminals are Amerada-Hess Oil Corp., Citmoco Service, Inc., Chevron Asphalt Company and Mobile Bulk Terminal, Inc. These terminals above the tunnels will not be affected by the channel improvement because of the limited depth of the tunnels. There are one public and three private bulk terminals below the tunnels used for docking deep-draft vessels and storage of cargo. No deep-draft vessel berths for handling general cargo are located below the tunnels.

The public general-cargo terminals occupy 6,000 feet of deepwater frontage on the west bank of the Mobile River beginning at the Bankhead Tunnel and extending to the Ideal Cement Company wharf, immediately north of Pier D. A total of 14,000 feet of deepwater berthing space for general cargo operations is available along the 26 berths. Terminals for handling dry bulk material being transported by deep-draft vessels are located on the west bank of the Mobile River, with the exception of a terminal for handling scrap iron which is located on the east bank of the river just south of Alabama Drydock and Shipping Company. One private terminal is located at the foot of Virginia Street which handles iron ore imports for reshipment to steel mills in Birmingham. The public grain elevator is located on Alabama State Dock property immediately north of Pier C. The Alabama State Docks
Department operates a bulk handling tipple and storage terminal which is located at the mouth of Three Mile Creek.

Bulk terminals for handling liquids are located on both banks of Mobile River within the harbor limits. Two oil terminals for handling crude oil are located at Magazine Point on the west bank of Mobile River just north of Three Mile Creek. Two other oil terminals are located on Blakely Island along the east bank of Mobile River. These latter two terminals are not major facilities for handling petroleum by tanker.

There are numerous other private and public facilities in Mobile Harbor that serve the port. These are dry and cold storage warehouses, open-storage areas, marine repair plants, towing companies, and the railroad companies discussed previously. The Terminal Railway, Alabama State Docks Department, performs switching service between the State Docks and industries along its rail lines to Chickasaw, Alabama. Connecting service with the line-haul carriers which serve Mobile is also provided by the Terminal Railway.

The Alabama State Docks Department is in the process of upgrading facilities at the grain elevator. This improvement will include the construction of a new truck court and scales, a 40,000 bushel per hour elevator leg, a 40,000 bushel per hour grain cleaning system, and a digital weighing system. Combined, they will allow grain to move through the elevator at twice the present rate. A recently completed, $6.0 million annex to the elevator will double the throughput of grain from rail/truck/barge to ship. Other completed improvements include a dust control system, a leg scale conveyor, a new pit for unloading rail cars, and a belt system extending from the barge unloading dock to the headhouse. Since 1975, total expenditures for upgrading facilities at the grain elevator have amounted to $16.0 million. The Alabama State Docks Bulk Ore Material Handling Plant, commonly
referred to as "The Tipple," is located on Mobile River and on the south side of the mouth of Three Mile Creek. This terminal has 13 acres of dry bulk storage with two ship berths. The annual throughput capacity of this terminal is estimated to be about 5.0 to 6.0 million short tons per year. The Alabama State Docks has under construction an expansion which will increase one of the unloading facilities to 1,500 tons per hour. Other improvements that have been completed include an upgrading of the structure and conveyor system, rebuilt docks, an upgrading of the power system, unloading towers, installation of dust control system, construction of new pile walls, extension of the conveyor system, and construction of new storage facilities. Total expenditures for this facility since 1970 total $12.8 million. The McDuffie Island Coal Terminal located south of the Bankhead and Interstate 10 Tunnels will, upon completion of facilities under construction, contain one ship berth and 70 acres of storage space. The facility is served by both barge and rail transportation. The annual throughput capacity of this coal terminal is estimated to be about 4.8 million short tons.

Commerce for Mobile Harbor for the 10-year period from 1966-1975 has shown a steady increase. The increase in internal barge traffic has been the most significant source of the increase. Foreign and coastwise traffic (deep draft) have shown a somewhat less significant increase in commerce. The major increase in deep-draft movements has been in the export of coal and coastwise shipments of crude petroleum. Trips and drafts of vessels using the harbor during the 10-year period from 1966 to 1975, as reported in "Waterborne Commerce of the United States," are discussed in greater detail in Appendix 5.

Human Resources. Mobile Bay's location and the area's mild climate have contributed greatly to the region's long, varied history. In 1819 Alabama was admitted to the Union and Mobile was granted a city charter. In 1861 Alabama seceded from the Union and was known as

the Republic of Alabama until it became a part of the Confederacy. Mobile was an important Confederate post and for three years the Union Navy blockaded the city in an attempt to stop trade. By the turn of the century manufacturing activities had grown but agriculture was still dominant. In 1923 the Alabama State Docks opened at the port and increased the city's importance as a shipping center. Today the area is experiencing another surge of growth as the popularity of the South as the "sun belt" attracts residents, industry and tourists alike.

Although the Mobile Standard Metropolitan Statistical Area (SMSA) is comprised of two counties, Mobile and Baldwin, 52 percent of the study area's total population resides in the city of Mobile.

In 1970 the Mobile SMSA had a population of 376,690 of which 72.2 percent were white and 51.9 percent were female. Nearly half the population was under 25 years of age, 8.3 percent were 65 and over, and 42.8 percent fell between these two age groups.

Education in the study area is provided by a system composed of public and private schools. In addition to elementary and high schools, there are two colleges, one university, two junior colleges, and a mix of vocational, technical and training schools.

The education level of Mobile SMSA in 1970 closely parallels the State level; however, both lagged behind the nation for the age group, 25 years and older, that are high school graduates. In the study area data on educational achievement in the above age group shows that 34.1 percent completed elementary school, 27.2 percent completed high school, 7.8 percent attended one to three years of college and 7.7 percent completed four years or more of college.
Historically the bay has been a focal point for people living in the area. A question which draws interest and opinions from the region's citizens is how to best utilize and yet protect Mobile Bay. The business community is a force for economic development in the area and regards the bay as an economic asset to be developed. The environmental action groups warn that development without regard for the ecological ramifications could lead to the degradation of the bay and a loss for all interests.

Natural Resources. Mobile Harbor is at the mouth of Mobile River where it enters the northwest extremity of Mobile Bay. The city of Mobile, located about 150 miles east of New Orleans, is on the west or right bank of the Mobile River near its mouth.

Coastal Alabama lies within the Southern Pine Hills and the Coastal Lowlands subdivisions of the East Gulf Coast Section. The Mobile Bay estuarine system occupies 466 square miles, including the lower Mobile River Delta. The third largest runoff volume in the continental United States enters Mobile Bay from a drainage area covering 44,000 square miles.

The shape of Mobile Bay (L-shaped) is significant in regard to the movement of water and sediment by both tides and wind. The long axis of Mobile Bay, as a continuation of the upland river flood plain and delta distributing system, is significant in regard to movement of freshwater floods from the rivers. The 31-mile fetch is also important in regard to generation of waves by wind from either the north or south. The restricted outlet into the Gulf of Mexico between Dauphin Island and Mobile Point (3 miles in width) exerts significant control on the movement of water and sediment by both wind- and tidal-generated currents.
Incoming tidal waters enter through the main pass between Dauphin Island and Mobile Point peninsula. The current is deflected to the east of the entrance and then gradually swings back to the west, finally flowing northward with the development of eddies in Bon Secour Bay. In the northern end of the bay, the river flow from the Mobile-Tensaw River system is deflected to the western side of the bay and continues to move down the bay even during flood tide. The circulation pattern is much simpler at ebb tide. The water in the entire bay moves predominantly south in a general clockwise circulation.

The tidal cycle in Mobile Bay is diurnal, usually with one high and one low tide in a 24-hour period. The mean diurnal tidal range in the bayous and inlets along the Alabama Coast varies from 0.6 to 1.8 feet. The mean tidal height in Mobile Bay varies from 1.5 feet at the head of the bay to 1.2 feet at the entrance. Since Mobile Bay is long and fairly wide, the tides are often overcome or accentuated by local winds.

Mobile Bay is 31 miles in length (not including 12.6 miles of delta) and has an average width of 10.8 miles. Within the estuarine zone, including the lower Mobile Delta, are 6,224 acres of tidal marsh, 12,000 acres of freshwater lakes, 15,127 acres in bayous, rivers and connecting bays, and 249,343 acres in the bay itself. The average depth of Mobile Bay is 9.7 feet and the maximum is about 60 feet off Fort Morgan near the gulf entrance to the bay.

Salinities in Mobile Bay change rapidly over a wide spectrum, from 0 to 35 parts per thousand. Major fluctuations in river discharge have an immediate effect upon salinity in all parts of Mobile Bay, although, if short-lived, the effects are usually expressed mainly in the surface portions of the water column.
The geomorphic characteristics of the Mobile Bay estuarine system are due to the processes of sediment deposition and erosion that have altered the estuary during its 3,500-year history. An annual average of 4.7 million tons of suspended sediment and an unknown quantity of bed load are currently being transported into the estuary. About 1.4 million tons pass through the estuary and are deposited to the south and west of the tidal inlet. Most of the fine-grained sediment from the Mobile Bay system is deposited to the south and southwest of the tidal inlet in response to the predominant littoral drift. However, during the summer months, an eastward component of the littoral drift system causes some of the silts and clays to move eastward.

Physically, the surface layer sediments of the ship channels in Mobile Bay range from sand and silt to inorganic silts and clays, most having the latter classification. The deeper sediments are somewhat coarser-grained with the upper bay channel containing the larger amounts of sand. Analysis of these sediments, including physical, chemical, heavy metals, bacteriological, and pesticides concentration are discussed in detail in Appendix 5, Section B.

Ecology and Environmental Quality. Vegetation located below the 12-foot contour is a complex and diverse mixture of marshes, barrier island dunes, unconsolidated wetland and swamps, urban and industrial lands, and perennially submersed marine grass beds.

The vegetated barrier flats are most evident and best developed along the gulf side of Dauphin Island and Fort Morgan Peninsula. The area offers a valuable resting, nesting, and wintering habitat for migratory waterfowl and shorebirds.

Tidal marshes are most extensive in the Mobile Delta and the northern shore of Mississippi Sound. Species composition varies as
salinity changes; i.e., the more brackish the water, the more salt-tolerant the plants. The brackish marshes are not only valuable as migratory waterfowl habitat, but also serve as a source of fixed carbon to surrounding waters, nutrient removal, and storm buffers.

The aquatic environment begins at the marsh with the major emergent estuarine plants and continues with areas of submersed vegetation. Submersed plants carry out several functions in aquatic environments including a food source for herbivorous animals and a place of refuge and source of food organisms for juveniles of many seafood species such as crabs, shrimp, and fishes.

The most sensitive areas to human disturbance in terms of diversity and abundance of commercially and aesthetically important invertebrates are the bay margins of the southern portion of Mobile Bay and Mississippi Sound; and the areas of highest oyster production, along the southwestern side of Mobile Bay. The area of least sensitivity would be the clayey bottoms of the bay centers and the upper third of Mobile Bay.

Mixing of the various water masses that enter Mobile Bay at regular intervals produces an infinitely varying combination of chemical and physical gradients. Generally, the bay's water temperatures range from about 10°C in January to about 31°C in August, while the average annual temperature is about 22°C. Bay salinities are generally low from January to May, ranging from less than 15 parts per thousand (0/00) in the lower bay to less than 5 0/00 in the upper bay. Summer and fall salinities range from 30 0/00 in the lower bay to 10 0/00 in the upper bay. A saltwater wedge extends from the mouth of the bay, up Mobile River and into Chickasaw Creek during most of the year.

Dissolved oxygen concentrations in the upper water column generally average about 7 mg/l. The lower limits of tolerance by aquatic
organisms are sometime reached, resulting in "jubilees" which occur during the summer, mainly along the eastern shore. The water quality of the bay waters is, for the most part, of sufficient quality to meet the applicable water quality standards. Perhaps the most significant problem is that of bacterial pollution which causes periodic closure of the commercial producing areas.

CONDITIONS IF NO FEDERAL ACTION TAKEN
(WITHOUT CONDITION PROFILE)

The without condition profile assumes the continuation of current trends and provides the base for the evaluation of future alternative impacts. Analysis of the no Federal action (No Action) alternative develops the no project impacts and effects upon the study area. Projections based on the "No Action" condition are presented in the following paragraphs.

Demographic Aspects. Without-channel modification projections for future growth in the study area indicate that the population of the Mobile SMSA will continue to increase from 377,439 in 1970 to 463,050 by 1995, and 502,500 by 2044. OBERS projections indicate that by the year 2000 the population in Mobile County will reach 388,700 and Baldwin County, 88,000. It is reasonable to expect that continued industrial growth in the study area will result in future population growth principally through immigration.

Regional Growth. Regional growth projections under present conditions for the SMSA are based on Series "E" national projections prepared by the Bureau of Economic Analysis. Employment and earnings by industry projections indicate continued economic growth under the "No Action" alternative and are summarized in Table 1. Total employment in the study area is projected to increase from 182,700 in 1995 to 204,800 in 2044. Earnings by industry are expected to increase

from $1.9 billion in 1995 to $4.1 billion in the year 2044. In 1995
the manufacturing sector is predicted to produce the highest earnings,
22 percent of the total, while the trade and service sectors earn 17
and 21 percent respectively. By 2044 the services sector is projected
to have the highest earnings (26 percent) followed by manufacturing
(21 percent) and government (17 percent).

Community Growth. Planning for future growth is a major problem
facing the Mobile SMSA. The South Alabama Regional Planning Commiss-
ion (SARPC) has proposed certain goals as the ends towards which
planned development may be directed. In summary these goals include:
(1) a wide variety of suitable housing, (2) ample land and facilities
to support economic growth, (3) protection, preservation, and enhance-
ment of the regions' major physical and environmental features, (4) a
permanent open-space system to provide recreational and agricultural
areas and a reserve for the protection and conservation of natural
resources, (5) an integrated regional transportation system, (6) land
use based on physical characteristics and location significance, and
(7) a sense of community identification and citizen participation in
local and regional affairs. General goals for regionwide community
services and human development have also been formulated.

If no Federal action is taken it is projected that future growth
in the study area will occur within developed suburban districts,
along major transportation facilities near urban areas, and close to
existing development-generating activities. Economic specialization
is expected to continue necessitating the development of specialized
employees. This trend is particularly applicable to downtown Mobile
which is predicted to continue as the area's center for finance, com-
munications, government, and service-related activities.

National Economic Development. Projections indicate that the
Mobile SMSA will maintain its role as the primary business activities
center in the 12-county BEA region. Because of its location at the hub of an Interstate highway, rail, and water transportation system, the city of Mobile is expected to retain its position as the wholesale trade center for the region. It is assumed that under the "No Action" the rate of growth for industries in the study area will at least equal or greater than the national growth rate.

**Transportation.** A comprehensive plan for the development of transportation facilities has been proposed for the study area by the SARPC. The estimated cost for implementing this plan has been set at over $1 billion, with highway facilities in the Mobile urban area accounting for more than 90 percent of the total costs. Mass transit systems are also being considered to relieve the ever-increasing traffic pressures placed upon the region's highways. The number of local commercial airline passengers is expected to increase tenfold between 1968 and 1995. To provide an adequate air transportation system for the area the expansion of the existing Bates Field Airport may be required, as well as the location of two additional airports in outlying areas. The Alabama State Docks has recently purchased 143 acres of waterfront property, rail lines, switching rights, and other facilities owned by the Illinois Central Gulf Railroad to facilitate better port-rail traffic conditions. The railroad rights-of-way and switching rights will be turned over to the Terminal Railway, which is also owned and operated by the State Dock. This action will open the McDuffie Island coal terminal equally to all railroads serving the area. It will also provide shippers with free and unobstructed access to all the existing and planned Mobile River terminal facilities.

**Projected Waterborne Commerce.** Annual commerce shipped through the Port of Mobile by deep-draft vessels has increased from 14.4 million tons in 1966 to 16.7 million tons in 1975. Barge traffic has increased from 7.9 million tons in 1966 to 15.8 million tons in 1975.
Upon completion of the Theodore Ship Channel (1982) 11.5 million additional tons of deep-draft commerce and 0.7 million tons of barge cargoes will be introduced into the harbor system. Assuming Federal action is not taken, it is reasonable to expect continued increase in deep-draft and shallow-draft cargo commerce as a result of economic expansion in the study area. Projections have been made for the annual volume of commerce moving in deep-draft vessels to the Port of Mobile. These data are shown in Table 2 and include projections for commerce expected to move over the Theodore Ship Channel, now under construction. It is estimated that the 1975 deep-draft tonnage, augmented by the Theodore tonnage, will increase to 59.5 million tons by 1995 and grow to 86 million tons by the year 2044.

Completion of the Tennessee-Tombigbee Waterway in 1986 will bring additional water-borne barge commerce to the study area. The waterway is projected to carry 28.1 million tons of commerce during 1986 and 34.6 million tons by 1993. Approximately 42 percent of the total traffic, or 11.8 million tons in 1986 and 15.2 million tons in 1993, will be imported or exported through the Port of Mobile. Expansion of terminal and barge handling facilities is expected to occur to meet the increased demand for these facilities.

Noise. Noise in the Mobile Harbor area results primarily from truck and automobile traffic and the operation of heavy machinery associated with loading and unloading at the docks. Since harbor activity is expected to increase without channel modification, it is assumed that noise levels will also increase. Completion of Interstate 10 across the bay lessens traffic noise. Traffic is flowing more evenly and the fact that the highway is elevated, and in an open space, aids in the dissipation of vehicular noise.

</table>
**Air Quality.** Even if no Federal action is taken, the study area will continue to experience a level of growth. Therefore, the Division of Air Pollution Control, Bureau of Environmental Health, which monitors Mobile County's air quality, is presently developing an Air Quality Maintenance Plan for the county. The plan, which is mainly concerned with particulates, will cover the twenty-year period from 1975 through 1995, and will indicate the ambient air levels resulting from this increased growth. It will then determine what, if any, additional regulatory measures will be necessary. New industrial development in the county will be subject to stringent regulations and extensive studies will be required to insure that the standards will not be violated as a result of the new development. Since most of the study area's industrial growth is expected to occur in Mobile County, Baldwin County is not projected to experience serious degradation to its air quality. It is also expected that when final compliance with Federal automobile emission standards is achieved, there will be a substantial reduction in the photochemical oxidant level. Stringent controls of new industrial development will also be necessary to assure this.

**Housing.** With or without the considered improvement, the present pattern of residential development is expected to continue, with heavy growth areas to be located west of the city of Mobile and south to Theodore. The completion of Interstate 10 across the bay should result in Baldwin County becoming more attractive to residential development.

A survey conducted for the South Alabama Regional Planning Commission indicates that, while there is a high demand for apartments in the city of Mobile, the greatest demand is for single-family dwelling units. The Planning Commission has established a number of housing goals including special home-purchasing assistance to low-income groups, rehabilitation of substandard housing, and the stimulation of a rate of housing construction adequate for an expanding population.
and to alleviate existing overcrowding. The commission also hopes to prevent "urban sprawl" by encouraging residential growth in geographical groupings balanced by permanent open spaces.

**Displacement of People.** As previously stated, the Mobile Harbor area is expected to require additional dock facilities without regard to deep-draft navigation improvements in the Mobile Ship Channel. There is little residential development in the project area. Most of the existing houses are in a delapidated condition and are currently subject to urban renewal programs. Therefore, increased dock activity is not expected to affect the displacement of residential dwellings.

**Aesthetic Values.** Assuming no Federal action is taken, aesthetic values in the project area are expected to undergo changes as the region responds to the need for industrially developed land and expanded harbor facilities. This expansion can be expected to reduce the amount of open-space lands and to render the area less desirable for recreational activities.

**Community Cohesion.** A decision against Federal action regarding the requested improvements should not significantly affect future community cohesion in the Mobile SMSA. Certain groups within the region would be pleased with this decision while others would regard rejection of harbor improvements as a blow to the economic well-being of the study area.

**History and Archeology.** A decision not to implement the modifications to the Mobile Ship Channel now under consideration would not affect historical or archeological resources in the study since no new construction would take place.

**Water and Land Use.** As the population in the study area continues to increase, more land now used for other purposes will be
converted to urban and built-up uses. This trend is expected to continue even with no additional harbor improvements. The bulk of new industrial development will probably occur as an extension of existing industrial areas in order to take advantage of existing power, water, highway, rail, or seaport facilities. Therefore, industrial growth is projected to expand primarily along upper Mobile Bay, north along the Mobile River, and south in the Theodore Industrial Park. Concomitant commercial development is expected to occur in the areas of residential development previously discussed.

Anticipated growth will create conflicting demands for the study area's fresh water resources. Much new industry is locating in the region to take advantage of this resource. Continued population growth will also require large amounts of fresh water.

**Projected Recreation Uses.** At present the general project area provides a variety of recreational opportunities, including hunting, fishing, swimming, boating, bird-watching, etc. Assuming no Federal action, projected industrialization and increased water-borne commerce is expected to claim further undeveloped land in the project area. Estuarine areas and wetlands along the bay may continue to be lost, reducing available wildlife habitat, resulting in a lowering of species diversity and population densities, and lessening recreational opportunities for the outdoorsman. Also, increased barge and deep-draft vessel traffic associated with economic growth and the Tennessee-Tombigbee Waterway may interfere with some water-oriented activities.

**Environmental Effects.** Some ecological trends occurring today can be expected to continue even without the structural modifications under consideration for the Mobile Ship Channel. The profile of existing conditions for Mobile Bay, outlined in Appendix 5, Section B, indicates that considerable environmental stress regularly occurs in
the bay's estuarine and marine ecosystem. The two most obvious indicators of this condition are the "jubilees" and the annual closure of the bay to the harvest of oysters. However, such events have been recorded since early historical development in the Mobile area.

In the absence of changes to the existing project, future maintenance would continue to be performed according to current practice. On an average, approximately 3,824,000 cubic yards of sediments would continue to be removed annually from the Mobile Bay Channel and placed in open water on both sides of the channel along its entire length. Approximately 2,000,000 cubic yards of material would continue to be removed from the Theodore Ship Channel and placed in the Theodore Island containment area. Approximately 225,000 cubic yards would continue to be removed from the bar channel and placed by hopper dredge over 4.4 square miles of open gulf bottoms. Approximately 1,150,000 cubic yards would continue to be removed from the river channel. Material from this reach is currently placed in contained areas adjacent to the upper harbor, however, future capacity is very limited. Severe environmental constraints tend to retard further development of upper harbor disposal sites into adjacent wetland areas. Plans to accommodate this future requirement are being developed by the project sponsor with technical assistance by the Corps of Engineers.

Disposal of material dredged from the bay channel will continue to disrupt the benthos within the disposal areas. Organisms include polychaete worms, nemertean, crabs, shrimp, mollusks, and echinoderms. Motile species normally either avoid or leave the disposal areas while the nonmotile forms are directly covered by the dredged material, mud flow, or heavy siltation within 1,200 to 3,500 feet from the disposal site. Since recovery of the benthos does occur, the total ecosystem loss resulting from this disposal technique has not been fully documented. Applicable studies to date indicate that it is a relatively
major impact well within the resiliency of the estuarine system provided that existing circulation patterns are not altered. The approximate community structure of the dredged and disposal areas is essentially fully reestablished within 9 to 18 months, after each maintenance operation. Since maintenance at any one reach repeats on a two-year cycle, significant recovery and utilization characterizes the disposal sites, prior to resumption of perturbation by dredging.

Maintenance dredging in the Mobile Harbor channels with disposal in open water also results in a temporary increase in turbidity. A study by Brett (1975) indicated that dredged material placed in open water stabilizes within a nine-month period and then becomes difficult to resuspend because of the high concentrations of clay particles. It was also concluded from the study that turbidity produced by dredging is transitory and lasts one to two days. This finding indicates a very short-term effect on light penetration and a consequent negligible effect on light-dependent plankton populations and sight-feeding fish. This effect is also minimized in Mobile Bay by the high natural state of turbidity.

Water quality is also affected by the high chemical and biochemical oxygen demands associated with finely sorted channel sediments. Resuspension of these sediments results in a temporary reduction in dissolved oxygen. The channel sediments contain moderately high concentrations of several trace elements. Windom (1973) concluded that dispersion of the sediments by dredging was not followed by metal release of any significant quantity, except possibly in the case of zinc and iron. It was further shown that variations in metal levels in the bay show no relation to dredging activities, but were more influenced by natural processes such as runoff. Increased levels of metals in the water column were found near the discharge end of the dredge pipeline, but were highly localized.
In order to determine the potential release of contaminants in the dredged material into the receiving water column, the Corps of Engineers and the Environmental Protection Agency developed the elutriate test. It is designed to quantify the increase in concentration of a given constituent in the proposed receiving water (dilution water) after a sediment sample has been added vigorously to the dilution water, simulating the actual dredging conditions. In 1974 surface layer sediment samples were collected from 27 stations in the Mobile Ship Channel to assess the effects of maintenance dredging and disposal of the material. Physical and chemical characteristics of these sediments are discussed in Appendix 5, Section C. Elutriate analyses (see Appendix 5, Section D) performed on eight of the sediment samples indicated that the nutrient-related constituents, such as ammonia nitrogen, total Kjeldahl nitrogen, dissolved phosphorus, and total organic carbon most often demonstrated a potential to be released into the water column. It was concluded, from a nutrient standpoint, that the release of the constituents would not be expected to create adverse water quality conditions in unconfined areas of Mobile Bay. A scavenging trend was noticed for metals in most of the samples analyzed, resulting in lesser concentrations in the elutriate waters than in the dilution or background waters. Based on the results of the elutriate test, it was found that there would be an increase in the concentrations of copper, cadmium, lead, nickel, and iron, but the increase would be limited only to the area of the immediate discharge.

The impact of disposal from the bar channel is similar to the open-water bay disposal. The primary difference is that the emptying of the hopper dredge within this area has resulted in a buildup of the sea bottom. The process generates large clouds of suspended solids upon deposition. The time required for the induced turbidity to dissipate has not been specifically documented, but it is considered to be less than one day. Solid material from the dumping action traps and smothers many organisms living in and traveling through the water.
column above the dumping grounds, as well as bottom organisms. Fish are frequently seen jumping from the water within the area of the turbid water. It is not known whether they are being pursued by larger predators and have sought cover within the turbid water or if they are jumping to avoid the increased turbidity.

Since both Sand and Dauphin Islands are presently experiencing some erosion problems, it is highly probable that the present maintenance project could be coupled with a beach nourishment program in the future. The principal impediment to the immediate implementation of such a program lies in the present lack of a sufficient number of hopper dredges which have pump-out capability. As more dredges with this capability become available, the material from the outer bar could be pumped into the littoral drift system of Sand and Dauphin Islands.

Two samples were taken along the bar channel during preparation of the Mobile Harbor Operation and Maintenance Environmental Impact Statement. The physical characteristics of both these samples are such that they are excluded from the requirement for elutriate analysis and are considered acceptable for open-water disposal. This material is characterized by a very high percentage of coarse sand with approximately 7% silts and clays. The silts and clays are responsible for the turbidity increases during the loading and unloading of the hopper dredge.

Disposal of dredged material along the Bay channel is thought to have modified circulation patterns in the bay (May, 1973). Jubilees are considered to be caused by salinity stratification in sinks created by shoals in the lower bay and by spoil banks from the ship channel. May reports that the natural shoaling and spoil from the channel have dammed most of the bottom water on the eastern side of the bay preventing its regular exchange with the gulf. Organic matter
and woody debris accumulate in these sinks, and bacterial decomposition of this organic matter during summer when waters are stratified causes oxygen depletion in bottom waters of the sinks which, under certain conditions, may move shoreward causing a jubilee. The mortality caused by this phenomenon has not been assessed, nor has its impact on the trophic dynamics of the bay ecosystem been established. Recent surveys by the Corps suggest that the buildup of material alongside the channel is not as extensive as has been previously thought. There has been a buildup of material in the upper third of the bay west of the ship channel and to a lesser extent on the east side. Evaluation of the surveys reveals that the presently existing volume of material along the channel is less than the volume of material involved in initial dredging alone. Consequently, it is considered that the lighter maintenance material does not accumulate but is redistributed by wind, wave, and tidal action. Disposal operations in the lower bay have not resulted in a significant accumulation of the dredged material. The Mobile Bay Technical Committee Report (1973) concluded that the apparent existence of depressed dissolved oxygen conditions prior to the construction of the ship channel indicates that the present physical modifications to the bay are not the sole causes of existing water quality conditions. The contribution that the ship channel and disposal mounds makes on circulation patterns and water quality conditions is not well defined.

PROBLEMS, NEEDS AND OPPORTUNITIES

The problems and needs examined relate to Mobile Harbor's ability to efficiently handle the present and future deep-draft commerce of the tributary area and ways to enhance and/or minimize adverse impacts upon the surrounding environment.
Public Concerns. A public meeting was held at Mobile, Alabama, on 25 April 1967, to afford local interests an opportunity to express their desires and to present their views and opinions regarding the advisability and justification for Federal participation in the improvements of navigation facilities for Mobile Harbor. The hearing was attended by 72 persons representing Federal, State, county, and local government agencies and other civic bodies, navigation interests, industry and local interests concerned with port development.

Proponents at the public meeting requested that the Federal project for Mobile Harbor be modified to include adoption and enlargement of the existing Theodore Channel to provide a channel 40 feet deep and 300 feet wide and that such channel be extended by land cut into a turning basin within the Theodore Industrial Park. Local interests further requested that the turning basin opposite Magazine Point in Mobile River be enlarged and that an anchorage basin of sufficient size to accommodate 12 large ocean-going vessels be provided near the mouth of Mobile River. Local interests also requested the Corps of Engineers initiate such studies as may be necessary to determine the engineering and economic feasibility of providing a 50-foot depth in the main Mobile Harbor channels. No opposition was expressed to improvement of the harbor, however, a request was made that all possible steps be taken to minimize adverse effects of dredged material disposal on fish and wildlife resources.

A second public meeting was held at Mobile, Alabama, on 22 November 1976 with over 140 persons in attendance. Alternative plans were presented for the disposal of dredged material, both for the new work and maintenance material which would result from the implementation of any channel improvement. All alternatives considered at this stage of the planning process were related to a 50-foot, deep-draft channel with commensurate widths, anchorage basins, turning areas, and auxiliary barge and access channels.
A considerable majority of those represented at the meeting were in favor of improvements for Mobile Harbor. State officials, representatives of shipping interests, and local citizens either spoke or wrote letters in favor of the project. However, several Federal and State agencies, environmental groups, and local citizens spoke or wrote letters expressing concern or opposition to several of the plans and certain dredged material disposal alternatives. Concerns included the necessity or desirability of deepening Mobile Ship Channel, the potential environmental degradation of the bay and environs and the possibility of invalidating the Mobile 208 studies being conducted to determine the optimum location of discharge points within the bay. The Environmental Protection Agency in general sums up the views of those opposed. This agency prefers that the dredged material be transported to an approved disposal site in the Gulf of Mexico. It also states that open-water disposal in the bay from both new work and maintenance dredging should be discontinued and that spoil island development and navigational channel improvements should be supported by data generated not only from a mathematical model but also from the existing physical bay model.

**Resource Management Needs.** The existing 40- by 400-foot navigation channel into Mobile Bay presents constraints to the efficient movement of commerce into Mobile Harbor and the use of larger, more economical vessels in this commerce. Currently, liquid and dry bulk carriers with dead weight tonnage ranging up to 88,000 tons, widths in excess of 128 feet and lengths in the order of 850 feet, and fully loaded drafts up to 43 feet are calling at Mobile Harbor. Because of the limiting channel depth of 40 feet, these large ships are calling at Mobile Harbor light-loaded with concomitant increased transportation costs. With improved channel depths and widths even larger vessels would use the harbor. There are also navigation problems and safety hazards associated with the channel widths, especially in the vicinity of McDuffie Island Coal Terminal.
At the present time there is a need for a turning basin in the vicinity of the McDuffie Island Coal Terminal. The Alabama State Docks Department dredged a turning basin on the east side of the channel approximately 27 feet deep, 800 feet long and 600 feet wide. The basin is adequate to turn light-loaded small vessels; however, the larger vessels must use a turning basin 2 miles up river opposite the Alabama State Docks.

Vessels calling at the Port of Mobile must wait their turn for their designated berth, at a terminal not in use, or anchor in the Gulf of Mexico. The lack of in-port anchorage areas prevents efficient utilization of the terminal's and hamper's overall port operations. The deficiency creates particular problems for the vessels awaiting berthing space at the liquid, dry bulk, or container terminals, that are too large to utilize unoccupied general cargo berths. An additional factor is the need for an anchorage as a matter of safety. There is currently no place in Mobile Harbor, away from terminal facilities, to anchor a ship that is broken down, or that presents a potential hazard or safety problem.

There are three main barge marshaling areas in Mobile Harbor at the present time. The two marshaling areas in the Mobile River are barely adequate to handle barge marshaling needs in that section of the port. The area in Garrows Bend at McDuffie Island must handle both loaded and unloaded barges. The area is presently estimated to be adequate for loaded barges while an area of equivalent size is needed for the marshaling and fleeting of empty barges. This area functions essentially in support of the McDuffie Island public coal terminal.

The current practice for disposal of dredged maintenance material from Mobile River is in diked disposal areas. Although objectionable to many interests, maintenance material from the Mobile Bay Channel is
deposited in open-water disposal areas along the channel within Mobile Bay. Due to environmental constraints preventing the use of wetland sites and due to industrial development, the areas for use as upland dredged material disposal sites are severely constrained. At the present containment areas only about sixteen additional years of maintenance dredging disposal can be accommodated. In view of the importance of continued operation of Mobile Harbor, there is a pressing, if not critical, need for a long-range disposal plan for dredged maintenance material from the Mobile River.

Several natural processes are occurring which affect the quality of the environment of Mobile Bay. The most significant is the natural sedimentation and filling of Mobile Bay. The inflow of sediment to the headwaters of the bay is greater than that which flows out of the bay to the gulf. Another natural process occurring on Mobile Bay is that of shoreline erosion. The shoreline around the bay varies from very stable to erosion rates in the order of magnitude of 10 feet per year.

The alteration of Mobile Bay by man has also created environmental problems. The construction of the causeway across the northern bay and delta introduced a barrier to the free flow and circulation of bay waters in addition to the introduction of pollutants from developments along the upper part of the estuary.

The above resource management needs (problems and opportunities) and other related needs constitute the basis for the planning objectives addressed in this study to enhance National Economic Development or Environmental Quality.
PLANNING CONSTRAINTS

Legislative and executive authorities have specified the range of impacts to be assessed, and have set forth the planning constraints and criteria which must be applied when evaluating alternative plans. Plans must be developed with due regard to the benefits and costs, both tangible and intangible, as well as associated effects on the ecology, and social and economic well-being of the region. Federal participation in developments should also assure that any plan is complete within itself, efficient and safe, economically feasible in terms of current prices, environmentally acceptable, and consistent with local, regional, and state plans. Plans which recommend non-structural alternatives must be given equal consideration, and as far as practical, plans should be devised which maximize the beneficial and minimize the adverse effects of the considered improvements.

PLANNING OBJECTIVES

Establishing planning objectives involves analyzing the identified concerns regarding the use of water and related land resources in the study area to translate them into specific objectives for the study. The data developed will be analyzed as a basis for translating needs, opportunities, concerns, and constraints into the planning objectives of the study. These objectives will be set forth and described as specifically as possible so as to provide a meaningful guide and focus for subsequent formulation activities.

Specific planning objectives for this study derive from Mobile Harbor's need to more efficiently and safely accommodate the larger vessels desiring to call at the port. To fully achieve these ends it is necessary to widen and deepen the ship channels, and to provide additional turning and anchorage basins. Also sought is a long-range
acceptable solution for dredged material disposal from the Mobile Bay and River sections of Mobile Harbor, the investigation of measures for shoreline erosion protection, and measures to preserve and enhance the water quality and related ecologic and recreational integrity of Mobile Bay.

The following planning objectives were applied in the first stage of the plan formula process.

- More efficient and safe movement of existing and projected commerce by deep-draft vessels.
- Maintain and enhance environmental quality.
- Compliment regional goals for development of water and related land resources.
FORMULATION OF PRELIMINARY PLANS

This section of the report contains a listing of the criteria used for plan formulation and evaluation, a discussion of the plan formulation methodology, a discussion of the plans developed by local interests, and a step-by-step development of preliminary plans to satisfy the need for deep-draft access to the Port of Mobile and to the Theodore Industrial Area, the need for a turning basin and anchorage area near the mouth of Mobile River, and the need for a barge marshaling area near McDuffie Island. The plans formulated during the preliminary planning stages are described and screened with a view toward determining which alternatives should be carried forward for further investigation.

PLAN FORMULATION RATIONALE

Federal policy on multiobjective planning, derived from both legislative and executive authorities, establishes and defines the national objectives for water resources planning, specifies the range of impacts that must be assessed, and sets forth the conditions and criteria which must be applied when evaluating plans. Plans must be formulated with due regard to benefits and costs, both tangible and intangible effects on environmental features and social well-being of the region, and with due regard to public acceptability and institutional capability for implementation.

Evaluation of alternative plans is aided by displaying in a system of accounts the effects on regional development and social well-being,
along with effects on national economic development and environmental quality. The regional development account embraces several types of beneficial effects, such as increased regional income and employment, population distributions, diversification of the regional economic base, and enhancement of environmental conditions of special regional concern. The beneficial effects on social well-being are contributions to the equitable distribution of real income and employment and to other social objectives. The display of effects in the four accounts provides a basis for comparing alternative plans and for indicating the tradeoffs among them.

In addition to evaluating the effects of alternative plans in four accounts, plans are appraised in terms of a set of "specified evaluation criteria."

**Acceptability.** Significant public support or strong opposition will be evaluated.

**Completeness.** Investments and actions which are not part of the plan but which are necessary to obtain the plan's outputs will be considered.

**Effectiveness and Efficiency.** These two related criteria center on the concept of achieving maximum net outputs where outputs and inputs are conceived broadly to include intangible factors. Effectiveness includes, in addition, the concept of technological feasibility.

**Certainty.** The likelihood of obtaining contributions claimed under the four accounts mentioned above will be evaluated.

**Geographical Scope.** This criterion requires that areas impacted beyond the study area whose main problems may be solved by the plan be indicated.
**NED Benefit/Cost Ratio.** This ratio, indicating economic efficiency, is always considered and displayed.

**Reversibility.** The degree of reversibility will be stated.

**Stability.** A judgment will be made of each plan's stability.

Technical criteria applicable to the study of Mobile Harbor improvements include:

- Structural improvements to the existing project must be consistent with local, regional and state plans for land use and port expansion.

- Improvements should have dimensions adequate to accommodate expected user vessels and have available facilities or expansion potential to accommodate projected traffic and commerce.

- Authorized project dimensions should recognize the present Federal policy that requires local interests to maintain berthing areas outside the boundaries of the Federal project.

Technical criteria for the Mobile Harbor channels are discussed in detail in Appendix 5, Section D.

Established economic criteria insure that the selected plan will be the most economical way of meeting the planning objectives. Those applicable to this study are:

- The plan must have net national economic development benefits unless the deficiency is the result of benefits foregone or additional costs incurred to serve the environmental quality objective.
• The plan, as ultimately formulated, should provide the maximum net benefits possible within the framework of the formulated concept.

• Costs of alternative plans are based on current unit prices.

• Benefits and costs should be in comparable economic terms to the fullest extent possible.

• Annual benefits and costs are based on a 50-year (1995-2044) amortization period and the current discount rate of 6-7/8 percent, as determined by the Water Resources Council, based on the cost of Federal long-term borrowing during the preceding 12 months.

• Plans should be formulated to maximize the beneficial and minimize the adverse effects of the project on:

Man-made resources
Water quality
Wetlands
Air quality
Aesthetics
Physical characteristics of Mobile Bay and the Gulf of Mexico
Long-term changes in Mobile Bay and the Gulf of Mexico
Biological productivity of the bay and gulf area
Structure of biological communities
Species diversity
Patterns of commercial harvest of fish and shellfish
• Plans should minimize and, if possible, avoid:

Destruction of community cohesion
Injurious displacement of people
Disruption of desirable community growth
Undesirable alteration of recreation opportunities

• Consideration should be given to protection of historic, archeological and other public interest areas.

• Plans should not significantly increase noise pollution during construction or create conditions that will tend to raise the overall noise level of the area over the life of the considered improvement.

Plans were formulated within the framework of an iterative, three-stage process: (1) Possible Solution, (2) Development of Intermediate Plans, and (3) Development of Detailed Plans. Each stage is composed of the same four functional planning tasks and maintains the same sequence of task performance, although emphasis shifts with successive iterations. Formulation advances through the stages until only those alternatives that could be implemented remain under consideration. The formulation methodology is illustrated in Figure 10. In coordination with concerned state and local representatives and private interests, further, more detailed analyses were conducted of those plans carried over from the initial stages and endorsed by local interests. As a result of those analyses the selected plan was derived.
PLANS OF OTHERS

A plan (see Figure 11) developed by a consulting firm hired by the State Docks Department was selected as the port expansion master plan. It features a realigned Arlington Channel and a parallel ship channel into the proposed land mass opposite Brookley, with areas in Garrows Bend and adjacent to the maintenance dredge material disposal areas available for barge marshaling. This expansion plan represents a continuous land mass consisting of McDuffie Island (expanded to 730 acres), to Garrows Bend/I-10 area (590 acres before detailed planning), and the proposed land mass opposite Brookley (approximately 2,340 acres) for a total proposed expansion area of 3,660 acres.
Phases I, II and III are in order of recommended development of the property and defined below.

Phase I - Preferably property under ownership of A.S.D. with soils conditions acceptable for immediate development. Facilities utilization must be commensurate with A.S.D. needs.

Phase II - Property that could not be economically developed at this time because of either poor soils conditions or delay in acquisition. It also includes a portion of the proposed land mass to be filled by use of dredge material.

Phase III - The remainder of the proposed master plan acreage which is all dredge-fill material.

The State Docks Department is actively pursuing this plan by purchasing land adjacent to Girrows Bend.

The South Alabama Regional Planning Commission, in accordance with Section 208 of Public Law 92-500, is currently responding to the need for a regional wastewater management plan for Mobile and Baldwin Counties. The critical water quality management needs of the region, identified and addressed in the 208 study, are listed below:

- The lower Mobile River segment with Chickasaw Creek and Three Mile Creek, because of point source discharges and the concentration of dischargers in this area.

- The upper part of Mobile Bay, because of the numerous semipublic and private discharges along the causeway and the eutrophication problem. This causeway also presents a prime area for resolution of an institutional problem. The permanent closure of the upper part of the bay to oyster harvesting and the dredging of the ship channel pose other problems to be addressed in the 208 study.
The Theodore area, and specifically the point and nonpoint discharges from an industrially developing area.

The nonpoint sources of discharge from urban industrial, commercial, residential, resort, agricultural, and silviculture areas.

The Alabama Coastal Area Board will review alternative plans to determine consistency with their plan for environmental protection and economic benefits to the project area. In general, their plan encourages economic growth with no environmental loss.

MANAGEMENT MEASURES

Specific features to be considered in formulating any plan include not only navigation improvements but also the possibility of investigating measures other than identified navigation problems. These measures are outlined below.

NAVIGATION MEASURES

- Deepen and/or widen the main ship channel.
- Widen and deepen the authorized Theodore Ship Channel.
- Provide and maintain a barge marshaling area in Garrows Bend.
- Provide an anchorage area near upper limits at Main Bay Channel.
- Provide a turning basin below the Interstate 10 tunnels.
- Reduce traffic delays with a passing lane.

DREDGED MATERIAL DISPOSAL MEASURES

- Construct islands or fill area adjacent to shore.
- Open-water disposal in the bay and gulf.
- Upland disposal sites.
- Recycle material off existing disposal sites.
- Abate shore erosion with dredged disposal material.
- **WATER QUALITY MEASURES**

  Remove obstructions to improve water circulation.
  Fill depressions in bay to improve water quality.

- **FISH AND WILDLIFE MEASURES**

  Improve areas adjacent to causeway.
  Establish additional oyster beds.

- **PORT DEVELOPMENT MEASURES**

  Offshore terminals
  Future expansion area
ANALYSIS OF PLANS CONSIDERED IN STAGE 1 AND 2 PLANNING

DESCRIPTION OF PRELIMINARY ALTERNATIVES

"No Action" Alternative. The "No Action" Alternative, as far as this study is concerned, is the development of the most probable future conditions that would exist if there were no Federal modification to the existing navigation project. There will be environmental, economic, and social effects associated with the "No Action" Alternative. These effects will be presented in the Stage 3 analysis of the detail plans. The Stage 1 presentation of the "No Action" Alternative is primarily concerned with the question of what happens to the existing and projected commodity movements and navigation traffic if no Federal action is undertaken to modify the Mobile Harbor, Alabama, project. Presented below are the possible scenarios:

- **Light-loading of large vessels** - The trend in vessel sizes in the world fleet is toward larger vessels. Many shipping companies which own larger ships use these larger vessels in harbors where the maximum loaded draft of the ship exceeds the channel dimensions of the harbor. In Mobile Harbor, this has become common practice for some bulk carriers. Ships with capacities up to 100,000 deadweight tons with potential loaded drafts considerably in excess of 40 feet presently call on Mobile Harbor. These vessels are light-loaded, thereby increasing the transportation costs to these shippers. This trend toward larger vessels and light-loading of these vessels would be expected to increase if no modifications were made to the existing navigation channels for Mobile Harbor.
• **Movement of smaller vessels at less efficiency** - If the channel depth remains at 40 feet for Mobile Harbor the channel will become more congested because most of the bulk commodity movements will be in greater numbers of smaller vessels. By maintaining transportation costs at higher levels, this congestion eliminates the possibility of economic advantage to the Mobile region in navigation transportation savings.

**Environmental Quality Alternative.** An inventory analysis was made to determine those environmental resources which should be preserved, enhanced, protected or approached with care. Of primary concern in the formulation of the EQ alternative was the management of Mobile Bay such that no degradation of the water quality or fish and wildlife resources would take place. The following paragraph contains measures that have potential environmental enhancement effects.

Existing maintenance of the entrance channel provides sand that can be utilized to restore the eroded beaches of Dauphin Island; the ridges along the upper bay ship channel can be removed and material placed such that it will abate shore erosion along the western shore of Mobile Bay; a portion of the material taken from the ridges can be placed such that it will fill depressions in Mobile Bay that cause stratification of water and lead to dissolved oxygen deficiencies; additional oyster beds can be established in areas found suitable for such; openings in the causeway can be created to improve the circulation in the bay area north of U.S. Highway 90; freshwater flow in Mobile Delta can be regulated to dilute the saline waters created by the existing ship channel; and an opening in the fill connecting McDuffie Island to the mainland can be removed to improve circulation in the Garrows Bend area.

**Navigation Development Alternatives.** Various alternative plans for improving navigation were formulated.
• Provide an enlarged channel to the Port of Mobile. This alternative would involve deepening and/or widening the Mobile Bar and Bay Ship Channel into the mouth of Mobile River. Because of the restrictions of the Bankhead and Interstate 10 Tunnels, deepening of Mobile River would not be considered north of the tunnels.

• Provide an enlarged channel into the Theodore Industrial Area. This would involve deepening and widening the planned Theodore Ship Channel from the authorized 40-foot-deep by 400-foot-wide Bay Channel and 40-foot-deep by 300-foot-wide land cut channel.

• Provide a turning basin opposite McDuffie Island.

• Provide an anchorage area just south of McDuffie and Little Sand Islands.

• Adoption of the Garrows Bend Channel and McDuffie Island barge marshaling area for maintenance.

• Provide a passing lane along the main Bay Ship Channel in the vicinity of the Theodore Channel in lieu of enlarging the entire bay channel to reduce traffic delays.

• Provide additional width at the upper end of the main ship channel to eliminate handling problems and safety hazards in the area.

Alternative Port Expansion Plans. The following options were evaluated:

• Offshore terminals for bulk commodities.

• Tracts presently owned by the Alabama State Docks Department or private interests.
• Land that can be purchased or created.

Dredged Material Disposal Alternatives. The following dredged material disposal alternatives were formulated:

• Mobile Bay Island or Fill Alternatives. The island and fill areas would be so designed to contain all new work and maintenance material for a 50-year period.

• Open-Water Disposal. Two open-water disposal concepts were considered. First was the removal of all new work and maintenance material to the Gulf of Mexico. Second was the disposal of all new work and dredged maintenance material along the channels in Mobile Bay in such disposal areas currently used.

• Upland Disposal. This alternative involves removal of all new work and dredged maintenance material for a period of 50 years to upland disposal sites.

COMPARATIVE ASSESSMENT AND EVALUATION OF PLANS

The development of intermediate alternatives focused on advancing more specific plans for Environmental Quality, the enlargement of the Mobile Ship Channel and the enlargement of the authorized Theodore Ship Channel. The barge marshaling area and its entrance channel were dropped from considered plans since they are considered local responsibilities set aside for a localized use of delivering coal to the McDuffie Terminal. The offshore facility concept was also dropped from further consideration due to the lack of effectiveness and efficiency. Alternatives for dredged material disposal evaluated at this stage of the planning process were arbitrarily related to a
50-foot deep-draft channel with commensurate widths, anchorage basins, turning areas and auxiliary barge and access channels. These efforts were oriented toward evaluating disposal plan effects on the bay's environment and the selection of the better plans to be applied with channel improvement alternatives.

Seven of the dredged material disposal plans formulated during preliminary studies were evaluated on a physical model of Mobile Bay located at the Waterways Experiment Station at Vicksburg, Mississippi. The primary environmental objective of the tests was to analyze the effect the larger channel and disposal alternative would have upon salinity values within Mobile Bay. Results of the model tests indicated that all plans caused similar salinity changes regardless of island placement. Generally, the changes under the low inflow conditions included an increase in salinity in the upper bay and a freshening of the lower bay areas.

The selection of plans for further consideration was based on the cost, environmental, and socioeconomic analyses performed, the input from the public at a meeting of the Mobile Harbor Advisory Committee on 5 August 1976, and a plan formulation public meeting held in Mobile, Alabama, on 22 November 1976. Inferior plans were eliminated and those which exhibited promise from cost, environmental, and socioeconomic standpoints were selected for further consideration. The rationale for these selections follows.

The Upland Disposal Plan was eliminated because of excessive costs and adverse socioeconomic and environmental effects. This plan was extremely expensive compared to the other alternatives. There were also severe socioeconomic and environmental effects associated with the large land areas required to store all of the dredged material over the life of the project.
A Theodore Rehandling Plan was investigated to determine if there would be savings by using the proposed Theodore disposal island as a place to store dredged material for drying and consolidation before transport to the Gulf of Mexico. In a detail investigation of this plan, the costs of double handling of the material made this plan more expensive than first indicated. Since this plan is very similar to the Mobile Bay Island or fill and Gulf Disposal Plan with transport of the maintenance material to the Gulf of Mexico, yet more expensive than this plan, the Theodore Rehandling Plan was eliminated from further consideration.

The Mobile Bay Island and Fill Plans which consisted of five plans with disposal islands in upper and lower Mobile Bay had both advantages and disadvantages. The major drawback for these alternative plans is that they are extremely expensive. This is due in large part to the fact that a sheetpile or bulkheaded wall is considered necessary to retain the material in lower Mobile Bay, making the large disposal island in the lower bay extremely costly. This plan has advantages since all of the new work and maintenance material would be contained within diked or bulkheaded disposal areas. However, these plans, as a total concept, were eliminated from further consideration, mainly due to the excessive cost.

The Open-Water Disposal Plan, where all the new work and maintenance material from the channel enlargement would be deposited along the existing channels in Mobile Bay, is the least expensive of all plans. This Open-Water Disposal Plan would cause environmental problems due to the extremely large quantities of new work material deposited alongside the channel. These deposits of new work material alongside the channel would physically divide the bay, totally change its circulation patterns, and water quality could be severely degraded in large areas.
INTERMEDIATE ALTERNATIVES

Four remaining disposal plans, along with the Shoreline Disposal Option which could be implemented with any plan, were selected for further analysis in Stage 2 of the planning process. These alternative plans along with the "No Action" Plan and Environmental Quality Plan are all considered worthy of further study and are discussed in subsequent paragraphs.

"No Action" Plan. The "No Action" Plan would involve no changes in the authorized navigation improvements for Mobile Harbor. Under this plan current trends in economic development, environmental quality, and port development would continue. The forecasted pattern of port development and economic and environmental conditions are based on the following assumptions regarding future conditions of the Mobile Harbor project.

- The authorized 40- by 400-foot channel to the Theodore Industrial Complex will be constructed.
- The current practice of open-water disposal of dredged maintenance material in Mobile Bay will continue.
- There will be a continuing and pressing need for disposal areas for dredged maintenance material from Mobile River.
- Port development for Mobile Harbor will take place in the vicinity of existing port facilities, at McDuffie Island, and along the Theodore Ship Channel in the Theodore Industrial Area.
- The commodities projected for the year 2044 will probably continue to move through the port of Mobile, although at greater costs and even though considerable traffic delays will occur due to the greater number of vessels.

63
The "No Action" Plan provides an alternative course of action for the citizens of the Mobile region and will provide the base condition from which the costs, benefits, and socioeconomic and environmental effects of all other alternatives are measured. No costs or economic benefits are associated with the "No Action" Plan.

Environmental Quality (EQ) Plan. This plan was formulated to address the concerns of the pilots that handle the larger deep-draft vessels in the present restricted bay channel and also known environmental concerns and opportunities. The plan would widen the existing main bay channel up to the mouth of Mobile River. This would provide a safer channel and reduce the probability of accidents.

The existing maintenance methods of Mobile Harbor would be modified as follows:

- Maintenance of the entrance channel provides sand that can be utilized to restore the eroded beaches of Dauphin Island.

- The existing ridges in the upper bay created by natural sedimentation and dredged material that was disposed of alongside the main bay channel can be removed and the material placed such that it will fill depressions in Mobile Bay that cause stratification of water. Existing and future maintenance in the upper and lower bay channel will be carried to the Gulf of Mexico for disposal.

All new work dredged material will be transported by dump scows to a gulf disposal site or utilized to abate shoreline erosion along the western shore of Mobile Bay. The circulation in the bay can be further enhanced by providing additional openings in the U.S. Highway 90 causeway and by providing an opening in the fill connecting McDuffie Island to the mainland. Also, freshwater circulation in Mobile Delta
can be modified to offset the effects of the existing saltwater wedge in the ship channel. These circulation alterations along with the idea of establishing additional oyster beds can be implemented with any structural plan; however, this will require detailed studies prior to their recommendation.

Brookley Expansion Area and Gulf Disposal Plan No. 1. This plan involves the construction of an expansion area in Mobile Bay, just south of McDuffie Island, adjacent to the Brookley Industrial Complex. An island would also be constructed on the east side of the ship channel extending southward from Little Sand Island. The expansion area adjacent to the Brookley Complex will contain the new work material from the enlarged channel in upper Mobile Bay and will also have space reserved for maintenance material from the upper bay. The island on the east side of the channel would be constructed with a ring dike of new work material from the enlarged Mobile Ship Channel and would be sized to contain 50 years of dredged maintenance material from Mobile River. New work material from the enlarged Theodore Channel and lower bay and bar channels would be transported to the Gulf of Mexico for disposal. The maintenance material from these same areas would also be transported to the Gulf of Mexico for disposal. This plan was formulated to minimize open-water disposal in the bay of new work dredged material and eliminate all open-water disposal of dredged maintenance material in the bay.

Brookley Expansion Area and Gulf Disposal Plan No. 2. This plan involves all the same elements as the Brookley Expansion Area and Gulf Disposal Plan No. 1 except that maintenance material from the lower bay channel and Theodore Channel will be disposed of in Mobile Bay instead of the Gulf of Mexico. Disposal of maintenance material from the lower bay channel will be in the currently approved maintenance areas on either side of the channel. After capacity of the Theodore disposal island is reached, the maintenance material from
the Theodore Channel will be disposed of south of the Theodore Channel and west of the lower bay disposal. Placing maintenance material in open water in the lower bay is not as environmentally acceptable as utilizing the gulf for disposal; however, the plan represents a realistic tradeoff due to the cost of transporting the material to the gulf. This plan in lieu of the unacceptable open-water disposal plan most closely meets the NED objectives.

**Gulf Disposal Plan No. 1.** This plan calls for the removal of all new work and dredged maintenance material from the enlarged Mobile Ship Channel and Theodore Ship Channel to the Gulf of Mexico. The maintenance material from the authorized 40- by 400-foot Theodore Industrial Channel would be placed in the Theodore disposal island being constructed in conjunction with the Theodore Ship Channel until its capacity would be reached. At such time that material would also be conveyed to the gulf for disposal. This plan makes no provision for storage of future maintenance material from the Mobile River channel, however, it is oriented toward the EQ objectives in that it eliminates all open-water disposal of dredged material in Mobile Bay. The tradeoffs of this plan are primarily the economic costs of transporting the dredged material to the gulf and the land enhancement benefits foregone.

**Gulf Disposal Plan No. 2.** This plan embraces all of the features of Gulf Disposal Plan No. 1 with the exception that maintenance material from the enlarged Mobile Ship Channel will all be discharged into Mobile Bay in accordance with current practice. Maintenance material from the Theodore Ship Channel will be disposed of in the disposal island and also into open water south of the Theodore Ship Channel and west of the Mobile Ship Channel.
CONCLUSIONS (SCREENING)

Implementation of any of the four channel deepening alternatives would cause about the same socioeconomic effects. Construction of Brookley Expansion Area Plans No. 1 and No. 2 would induce more industrial development and port expansion in this area than would occur with the EQ or Gulf Disposal Plans. The four channel deepening plans would create an economic advantage for the Port of Mobile in comparison to other ports. The economic advantages would result in an increase in original economic and industrial development and would result in increased employment and demographic growth. Economic growth and port expansion would occur at a slower rate in the absence of deeper ship channels to Mobile and Theodore. Either plan as compared with "No Action" has significant national and international effects in terms of world resource distributions and import-export balances. The preliminary environmental effects assessment of the channel deepening plans as compared to the "No Action" (no development) Plan are presented in Table 3. The cost analysis performed at this stage of the planning process was to the detail required to compare alternative plans fairly. The Stage 2 plans were not designed in detail but continued to be somewhat conceptual in nature. For this reason, the cost and benefit estimates for Stage 2 plans were not detailed in scope and serve only for relative comparison. These benefits and cost indicators are also given in Table 3. Further studies are required at this time to assess the costs and benefits of the Channel Widening (EQ) Plan.

1/ Conclusions based on interpretation of results of model studies with all channels modified (also see Disposal Alternatives, Salinity Gradients).

2/ Studies are currently being conducted to determine the effects on ground water of construction of the Theodore Channel.

3/ Due to the changing state of guidelines and regulations, further studies may be warranted in the future.

4/ A study is currently being conducted to analyze the buildup of dredged material placed adjacent to the channel and its effect on water circulation.

5/ Results based on model studies with the depth and width of the main channel through Mobile Bay and the Theodore Channel being 50 feet x 500 feet.

**ALTERNATIVES ELIMINATED**

Certain alternative plans and measures of improvement to Mobile Harbor have been excluded from consideration because of inefficiency or their failure to meet the indicated needs in the study area. These alternatives are discussed in the following paragraphs.

**Gulf Disposal Plan No. 2.** This plan provides for placing maintenance material from the enlarged Mobile Ship Channel and Theodore Ship Channel in Mobile Bay. This plan neither yields the maximum net benefits, provides storage for maintenance from Mobile River, or meets the planning objective of improving water circulation in the bay.
Shoreline Disposal Option. A survey of property owners along the western shore of Mobile Bay was made to determine the interest in placing dredged material along the shoreline to abate the existing erosion problem. Various objections expressed included environmental damage, aesthetic degradation, and restriction of riparian rights. A tabulation of these comments clearly indicated that such a solution was not desired or acceptable by the majority of shoreline property owners.

A detailed cost estimate and benefit analysis was made to compare the level of development for each alternative selected for further study. At this stage of the study it became apparent that multiple use of a deeper channel into the Theodore Industrial Park and commodity movements to incrementally justify the enlargement could not be assured; therefore, no further consideration of this channel segment was made. Also, the cost estimates show it is not cost effective to construct an island on the east side of the upper bay channel below Little Sand Island to contain annual dredged disposal material. Transporting the maintenance material to the gulf is a more feasible alternative to the cost of constructing and protecting disposal island dikes. Costs developed for the detailed plans are based on the gulf dredged material disposal site being located within a 16-mile radius of the mouth of Mobile Bay.
The plans retained for further analysis are all considered implementable. They were evaluated in terms of acceptability, completeness, effectiveness, efficiency, and optimization. The plans were also evaluated with respect to meeting specific study area needs as well as the national planning objectives, accounts and constraints. Pertinent data and necessary analysis to establish optimum development levels are presented in Appendix 5, Section D. Descriptions and evaluations of the alternatives are presented in the following paragraphs.

"NO ACTION" PLAN

Plan Description. The "No Action" Plan would involve no changes in the authorized navigation improvements for Mobile Harbor. Under this plan, current trends in economic development, environmental quality, and port development would continue.

Evaluation and Assessment. The "No Action" Plan provides an alternative course of action for the citizens of the Mobile region and will provide the base condition from which the costs, benefits, and socioeconomic and environmental effects of all other alternatives are measured. No additional costs or incremental positive economic benefits are associated with the "No Action" Plan. An analysis of this alternative shows that more than 17 million dollars a year as an average will be lost from traffic delays. Since the present trends in deep-draft shipping are toward use of larger vessels, the existing and projected problems could be expected to become more acute.
Plan Description. This plan provides for deepening and widening the entrance channel and the main bay channel, providing an anchorage area near the upper limits of the main bay channel, and providing a turning basin opposite McDuffie Island. This plan involves the construction of a fast land expansion area in Mobile Bay, just south of McDuffie Island, adjacent to the Brookley Industrial Complex. New work material dredged from the upper 7.4 miles of bay channel, the anchorage area and turning basin would be utilized to construct dikes along the perimeter of the Brookley disposal area and to construct fast land. The remainder of the new work material from the upper bay reach above Theodore Channel intersection would be transported by hydraulic pipeline dredge to fill the southern portion of the Brookley disposal area. New work material from the lower bay and entrance channels would be transported with dump scows to the Gulf of Mexico for disposal (see area 1, Figure 12). The existing and future maintenance dredged material from the main bay channel would also be transported to the Gulf of Mexico for disposal (see area 2, Figure 12). This plan was formulated to provide additional fast land for harbor development, minimize open-water disposal of new work dredged material in the bay, and eliminate all existing and future open-water disposal of dredged maintenance material in the bay.

Derivation of the optimum level of channel development required a detailed analysis of shipping needs, commodity movements and projections, and an economic analysis of vessel fleets that would operate with various channel widths and depths. These studies indicate that maximum net benefits could be achieved from a channel with dimensions commensurate with a 55-foot depth main channel through Mobile Bay. A comparison of annual benefits, annual costs and net benefits for the 45-, 50-, 55- and 60-foot levels of development for the Brookley

</table>

The optimum level of development for the Brookley Expansion Area and Gulf Disposal Plan No. 1 (Modified) would provide a channel 57 feet deep and 700 feet wide in the entrance channel and a channel 55 feet deep and 550 feet wide through Mobile Bay. Also, commensurate depth would be provided at the anchorage area opposite McDuffie Island and the turning basin to be provided in that vicinity.

With implementation of the 55-foot level of development approximately 1,047 acres of fast land constructed to an elevation of approximately 17.5 feet above mean low water and 663 acres constructed to an elevation of approximately 15 feet mean low water of softer new work material would be provided adjacent to the Brookley shoreline. This development is compatible with the Alabama State Docks' long-range development plan and will provide, on the average, $2,697,000 in annual regional land enhancement benefits. McDuffie Island would not be used to dispose of additional dredged material due to its relatively low capacity and the marsh land that would be destroyed.
Evaluation and Assessment. Each of the structural plans carried forward for detailed investigation provides for modification of the Mobile Harbor and Ship Channel. These modifications would result in additional deep-draft transportation savings which should strengthen the regional and, to a lesser extent, national economies. While the improvements would tend to encourage the location of business and industrial activities in the general area, the effect is not anticipated to be significant enough to alter the current development trends and land use patterns in the area.

The optimum level of development for this plan would be provided and maintained at an additional annual cost of $22,028,000. Net benefits from the plan would be $11,102,000. This plan would provide for disposal of the 143 million cubic yards of new work material as well as all future maintenance material over the 50-year economic life of the plan. Approximately 65.3 million cubic yards of new work dredged material would be placed in the diked disposal area in the upper bay and 77.8 million cubic yards of new work material will be transported to the gulf for disposal. An average of 4.7 million cubic yards of dredged maintenance material will be transported annually to the gulf for disposal. This includes 4 million cubic yards for the existing project and 0.7 million cubic yards induced by the alternative plan.

Direct Benefits. Direct benefits that would be realized under this alternative plan are in the form of deep-draft transportation savings and land enhancement. Transportation savings will be realized during the construction period; however, for the purpose of this study these benefits were not considered. Also, the improved efficiency of the harbor will eliminate traffic delays due to constrained one-way traffic in the main channel, lack of anchorage areas in the upper harbor and limited turning areas.
Socioeconomic Impacts of the Considered Plan. As discussed in Appendix 5, Section D, certain socioeconomic trends expected to occur in the area under the "No Action" Plan would be induced with construction of this alternative plan. There would be an increase in population, employment, housing, industrial and commercial development, water-borne commerce, and port expansion. As the population in the study area continues to grow more land now used for other purposes will be converted to urban and built-up uses. This is particularly true for the heavy growth areas west of Mobile and south of Theodore. Baldwin County is also becoming more attractive to residential growth. Concomitant commercial development is expected to occur in the areas of residential development. The location of the industrial spine in Mobile is not expected to change significantly, although the demand for industrial land will increase. Industrial growth is projected to expand primarily along upper Mobile Bay, north along the Mobile River, and south in the Theodore Industrial Park. Expansion of port terminal and handling facilities is also expected to occur with the proposed upper bay disposal site being a primary area of expansion.

Demographic Aspects. Any population increase as a result of deepening the main ship channel would be insignificant to the BEA region or the Mobile SMSA. Any increase that might result from the implementation of the Brookley fill area would occur in the SMSA.

Population Mobility. The increased level of industrial and commercial activity in the project area is expected to be accompanied with an immigration of population to the SMSA.strained migration could occur in the immediate project area, however, if adverse environmental effects were to result from implementation of the project or residential properties were purchased for industrial or commercial use.
• National Economic Development. Implementation of a channel deepening plan would enhance national economy by improving transportation and handling facilities for ores and coal, among other items. The plan should also improve U.S. competition in foreign trade in these items. Transportation savings for imported materials would enhance the manufacturing competitiveness of the products proposed with the above bulk and other items.

• Noise. Noise from highway traffic and industrial activities is not significantly high at present, but the level of noise from these sources is expected to increase in the project area as a result of project implementation. Noise from other sources is either negligible or of short duration. Construction noise, for example, may be intense, but is of only a temporary nature.

• Aesthetics. Aesthetic effects which can be attributed to the Brookley expansion plans generally fall into three categories: visual effects, odor and noise. Because of the disposal of dredged material adjacent to the Brookley shoreline human activities associated with terrestrial aesthetic pursuits would be affected. Conversion of land use would be rendered less desirable for residential and recreational use from the standpoint of aesthetic amenities.

• Housing. Adequate land is available in the surrounding areas for residential developments associated with any population increase.

• Displacement of People. Student housing units are located on State property adjacent to the proposed Brookley fill area. The State is aware that such developments in their immediate vicinity would not take place for a number of years and therefore the residents can be relocated without any significant social impact.

• Health. The location of additional port facilities and increases in the number of workers in the area will increase the
chances of industrial accidents. There is no apparent shortage of health facilities in this area.

- **Community Cohesion.** Since the implementation of the Brookley fill area implies the displacement of some people, community cohesion as it now exists in the immediate project area would be disrupted to a certain degree. The quality of life, life styles, and the relationships between persons in the community at large are not likely to change.

Selection of this plan would not be expected to significantly affect community cohesion in the Mobile SMSA. Certain groups within the region would regard the harbor improvements as a major boost to the economic well-being of the study area while others would be skeptical of alterations to the bay.

Anticipated growth will create conflicting demands for the study areas' freshwater resources. Much new industry is locating in the region to take advantage of the resource. Continued population growth will also require large amounts of fresh water.

- **Water Quality.** Control of water pollution associated with the increased development of the area will be a major concern. As indicated in Appendix 5, Section B, a water quality management plan for Mobile and Baldwin Counties has been developed by the South Alabama Regional Planning Commission in compliance with Section 208 of PL 92-50C. In order to effectively improve water quality and assure attainment of water quality goals, the 208 study indicated that a regional structure is needed to coordinate the various city and agency water quality plans and standards. Such a structure would also facilitate the study of point and nonpoint sources of pollution and other water quality problems from a basin-wide perspective on a continuing basis. If the recommendations of the 208 study are adopted locally, certified by the Governor and approved by the Environmental Protection Agency, then the South Alabama Regional
Planning Commission, in conjunction with the Alabama Water Improvement Commission, will be assigned the responsibility to carry out the area-wide management program.

- **Air Pollution.** Since the study area is predicted to experience a continued growth level, the Division of Air Pollution Control, Bureau of Environmental Health, which monitors Mobile County's air quality, is presently developing an Air Quality Maintenance Plan for the county. The plan, which is mainly concerned with particulates, will cover the twenty-year period from 1975 through 1995, and will indicate the ambient air levels resulting from increased growth. It will then determine what, if any, additional regulatory measures will be necessary. New industrial development in the county will be subject to stringent regulations and extensive studies will be required to insure that the standards will not be violated as a result of the new development. Since most of the study area's industrial growth is expected to occur in Mobile County, Baldwin County is not projected to experience serious degradation to its air quality. It is also expected that when final compliance with Federal automobile emission standards is achieved, there will be a substantial reduction in the photochemical oxidant level. Stringent controls of new industrial development will also be necessary to assure this.

- **Environmental Effects.** Primary environmental impacts of this plan would be associated with: (1) channel construction and subsequent maintenance dredging operations, (2) construction and stabilization of the expansion area in the upper bay, and (3) offshore disposal of dredged material. A discussion of these impacts is contained in Appendix 5, Section D.

**Potential Mitigation Measures.** During the public meetings and work level conferences held during Stage I and II planning for this project, several measures were suggested by environmental agencies and groups which could be utilized to mitigate environmental damages.
resulting from any plan to deepen the Mobile Ship Channel. These measures include:

- Establish oyster beds in Bon Secour Bay.

- Improve water circulation in Mobile Bay by creating openings in ridges paralleling the main ship channel from Dog River to Mobile River.

- Restore tidal action in Chacaloochee Bay and Polecat Bay.

- Fill depressions which exist in Mobile Bay.

- Establish a recycle plan to remove material from existing Blakely and Pinto Island disposal areas.

- Replace wetlands destroyed.

- Provide better circulation behind McDuffie Island.

Since this plan would remove a significant quantity of shallow water bottom from production, this has been considered an important aspect for mitigation. Chacaloochee Bay was effectively removed from interaction with Mobile Bay by construction of the Mobile Delta Causeway. Tidal exchange is restricted to four 10-foot by 5-foot culverts passing under the highway. In order to provide full tidal flushing, almost the entire causeway across its mouth would require bridging. This is not considered feasible and may not be desirable for environmental reasons since the bay presently is heavily used by both sport fishermen and duck hunters. However, provisions for a partial restoration of tidal exchange would retard the rate of filling of the bay, provide a degree of control of undesirable aquatic plants, Eurasian milfoil along the northern boundary of the causeway, and restore much of the nursery value of the lower bay.
This measure could be implemented without additional model studies if the differing goals of the freshwater sportsman and the estuarine advocate could be resolved.

The establishment of oyster beds in Bon Secour Bay is not considered to be a desirable mitigation measure at this time, since the Bon Secour Bay has a historical record of very poor spatfall. Thus, it is doubtful that any reefs established would be self-maintaining. However, the circulation changes which would be induced by channel enlargement could greatly enhance this potential. Additional study is required.

Efforts to alter existing circulation patterns by opening channels in the upper bay or by filling the depression on the eastern side of the ship channel are viewed with reservation. Such actions have the potential of changing the long-term water quality of the bay in a positive manner. However, on the other hand, a certain amount of oxygen depletion is required if "jubilees" (fish move out of the water up on the shore) on the eastern shore are to continue. If the impact on larval forms is considered, "jubilees" may not be a bonanza as is commonly thought. Further investigation is required prior to implementation.

Approximately 70 acres of wetlands would be destroyed by constructing the Brookley fill. This loss will be mitigated by creating wetlands adjacent to the proposed fill.

The fill placed between McDuffie Island and the mainland will be opened to provide circulation behind McDuffie Island that has been partially blocked by the proposed Brookley fill area.

**Implementation Responsibilities.** Responsibility or development of this plan is divided between Federal and non-Federal interests in accordance with established policy and guidelines. The Federal
Government may construct or improve channels and harbors to meet the requirements of shipping, while non-Federal interests are responsible for terminal facilities, berthing areas, certain other components, and specified items of local cooperation.

The United States would design and prepare detailed plans, dredge the improved gulf and bay channels and turning and anchorage basins, and maintain the improvements to project dimensions, after Congressional authorization and funding.

Local interests would provide all lands, easements and rights-of-way; all relocations and alterations of utilities; all retaining works and stabilization measures required for disposal of dredged material; and depths in all berthing areas commensurate with those provided in related project areas.

Total average annual benefits for the 55-foot plan are evaluated at $33,130,000 including $30,433,000 navigation benefits and $2,697,000 land enhancement benefits. Land enhancement benefits are considered local and the cost allocated to land enhancement is a local responsibility. The benefits are summarized and allocated in Table 5.

The first cost of general navigation facilities for the 55-foot channel plan considered herein, excluding navigation aids, would be borne jointly by the United States and local interests. The apportionment is based on the ratios of "general" to "local benefits." According to the ratio of general to local benefits derived heretofore, 91.9 percent of the first cost of general navigation facilities would be borne by the Corps of Engineers and 8.1 percent by local interests.

The President, in his June 1978 water policy message to Congress, proposed several changes in cost-sharing for water resources projects to allow states to participate more actively in project implementation decisions. These changes include a cash contribution from benefiting states of 5 percent of first costs of construction assigned to nonvendible project purposes.

Application of this policy to this Mobile Harbor plan requires a contribution from the State of Alabama of an estimated $14,201,000 in cash (5 percent of $284,014,000 total estimated project first costs assigned to nonvendible project purposes, based on October 1978 price levels). Other items of local cooperation would not be affected by this additional requirement.

Estimated first costs, shown in Table 6, are based upon October 1978 dollar values. This table includes advance engineering and design costs, and the contributions required by local interests.
The presently estimated additional Federal annual maintenance is $1,424,000 which includes annual costs to the U.S. Coast Guard of $4,000 for maintenance of navigation aids. The estimated non-Federal average annual maintenance is $304,000.

BROOKLEY EXPANSION AREA AND GULF DISPOSAL PLAN NO. 2, MODIFIED (NED)

**Plan Description.** This plan was retained as that plan which maximizes NED efficiency. The plan provides for deepening and widening the entrance channel and the main bay channel, and provides a turning basin opposite McDuffie Island. The gulf entrance channel would be constructed by hydraulic hopper dredge and the material placed in the gulf disposal site. New work material dredged from the

upper 7.4 miles of bay channel, the anchorage area and turning basin would be utilized to construct dikes along the perimeter of the Brookley disposal area and to construct fast land within the northern portion of the disposal area. The remainder of the new work material from the upper bay reach would be transported by hydraulic pipeline dredge to the southern end of the diked disposal area. New work material from the lower bay reach would be loaded on dump scows by a hydraulic cutterhead dredge and transported to the gulf for disposal in deep water. The maintenance material from the upper bay will be transported to the gulf for disposal and the maintenance material from the lower bay channel will be disposed of in the existing sites presently used for maintenance of the lower main bay channel. The gulf disposal sites are the same as shown on Figure 12.

**Evaluation and Assessment.** As with the preceding alternative, optimization studies were performed to determine the level of development that would maximize net benefits. These studies indicate that maximum net benefits could be achieved from a channel with dimensions commensurate with a 55-foot depth main channel through Mobile Bay. A comparison of annual benefits, annual costs and net benefits for the 45-, 50-, 55- and 60-foot levels of development for the Brookley Expansion Area and Gulf Disposal Plan No. 2 is displayed in Table 7.

The optimum level of development for the Brookley Expansion Area and Gulf Disposal Plan No. 2 (Modified) would provide a channel 57 feet deep and 700 feet wide in the entrance channel and a channel 55 feet deep and 550 feet wide through Mobile Bay. Also, commensurate depths would be provided at the anchorage area opposite McDuffie Island and the turning basin to be provided in that vicinity.

Approximately 1,047 acres of fast land constructed to about +17.5 feet above mean low water would be provided adjacent to the Brookley Industrial Complex. The plan would provide a disposal area for soft new work material dredged from the southern portion of the upper main bay channel. This development is also compatible with the Alabama State Docks' long-range development plan and will provide, on the average, $2,697,000 in annual regional land enhancement benefits. McDuffie Island would not be used to contain dredged material because of its limited capacity and the marsh areas that would be destroyed.

The Brookley Expansion Area and Gulf Disposal Plan No. 2 (Modified) is the most economical of the detailed alternatives that meets the navigation needs of the area. Environmental impacts of
this plan would be identical to those of the Brookley Expansion Area and Gulf Disposal Plan No. 1 (Modified) except for the impacts related to disposal of maintenance material from the lower bay. At intervals of two to three years approximately 12,000 acres of lower bay bottom adjacent to the main ship channel would receive dredged maintenance material. This technique is presently employed for maintenance of the existing project. The 55-foot level of development as proposed would increase the average annual quantity of material dredged from the lower bay by about 150,000 cubic yards. Thus, a total of about 2.7 million cubic yards of maintenance material would be disposed adjacent to the channel annually.

The most significant concern about disposal of larger quantities of maintenance material in the lower bay would be associated with the physical fate of the material. Evaluation of previous disposal in the bay indicates that for the period of record, 1960 to 1976, approximately 49,600,000 cubic yards of dredged material were disposed in the lower bay including 13,000,000 cubic yards of material from channel modification. Bathymetric surveys of the disposal areas indicate that there has been a relatively small amount of accumulation of the material. Judging from this information it is expected that the increased quantities of maintenance material would also tend to be redistributed by wind, wave, currents, tidal action, or fisheries activities. As discussed under the "No Action" Plan in this section, studies to date indicate that the present practice of disposal of maintenance material adjacent to the channel results in a relatively minor biological impact, considered to be well within the resiliency of the estuarine system. This plan would result in only a relatively small increase in the present amount of material being deposited into the bay. Further studies would have to be conducted before recommending this alternative. Due to the environmental acceptability of gulf disposal over bay disposal this alternative has been dropped from further study.
Mitigation Measures. (Same as the Brookley Expansion Area and Gulf Disposal Plan No. 1, Modified.)

Implementation Responsibilities. Responsibility for development of this plan is divided between Federal and non-Federal interests in accordance with established policy and guidelines. The Federal Government may construct or improve channels and harbors to meet the requirements of shipping, while non-Federal interests are responsible for terminal facilities, berthing areas, certain other components, and specified items of local cooperation.

The United States would design and prepare detailed plans, dredge the improved gulf and bay channels and turning and anchorage basins, and maintain the improvement to project dimensions, after Congressional authorization and funding.

Local interests would provide all lands, easements and rights-of-way; all relocations and alterations of utilities; all retaining works and stabilization measures required for disposal of dredged material; and depths in all berthing areas commensurate with those provided in related project areas.

Total average annual benefits for the 55-foot plan are evaluated at $33,130,000 including $30,433,000 navigation benefits and $2,697,000 land enhancement benefits. Land enhancement benefits are considered local and the cost allocated to land enhancement is a local responsibility. The benefits are summarized and allocated in Table 8.
The first cost of general navigation facilities for the 55-foot channel plan considered herein, excluding navigation aids, would be borne jointly by the United States and local interests. The apportionment is based on the ratios of "general" to "local benefits." According to the ratio of general to local benefits derived heretofore, 91.9 percent of the first cost of general navigation facilities would be borne by the Corps of Engineers and 8.1 percent by local interests.

The President, in his June 1978 water policy message to Congress, proposed several changes in cost-sharing for water resources projects to allow states to participate more actively in project implementation decisions. These changes include a cash contribution from benefiting states of 5 percent of first costs of construction assigned to nonvendible project purposes and 10 percent of costs assigned to vendible project purposes.
Application of this policy to this Mobile Harbor plan requires a contribution from the State of Alabama of an estimated $4,201,000 in cash (5 percent of $284,014,000 total estimated project first costs assigned to nonvendible project purposes, based on October 1978 price levels). Other items of local cooperation would not be affected by this additional requirement.

Estimated first costs, shown in Table 9, are based upon October 1978 dollar values. This table includes advance engineering and design costs, and the contributions required by local interest.

The presently estimated additional Federal annual maintenance is $1,363,000 which includes annual costs to the U.S. Coast Guard of $4,000 for maintenance of navigation aids. The estimated non-Federal average annual maintenance is $304,000.

GULF DISPOSAL PLAN NO. 1

Plan Description. The Gulf Disposal Plan No. 1 would enlarge the channels and construct the anchorage area and turning basin, as

do the Brookley Expansion plans. This plan differs in that new work and maintenance material from the upper bay would be transported by dump scows and disposed of in the deep water of the gulf. The diked bay disposal area would not be constructed. New work and maintenance from the lower bay would also be disposed of in the deep water of the gulf. The plan would reduce the present net rate of sedimentation in the bay and would prolong the bay's estuarine life; however, this plan does not provide any fast land development for future port development in the upper bay.

**Evaluation and Assessment.** As with the preceding two alternatives, optimization studies were performed to determine the level of development that would maximize net benefits. These studies also identified the 55-foot level of development for the main bay channel as the optimum plan. A comparison of different levels of development for the Gulf Disposal Plan No. 1 is displayed in Table 10.

</table>
The Gulf Disposal Plan No. 1 varies from the preceding plans for constructing areas in upper Mobile Bay for dredged material disposal in that the plan provides for disposal of all the new work and maintenance in the deep water of the Gulf of Mexico. Other aspects of the plan in regard to the channel construction would be the same.

The plan would involve disposing 143 million cubic yards of new work material and an average of 4.7 million cubic yards of maintenance material annually in the gulf. The optimum level of development for this plan could be constructed and maintained for $25,787,000 annually. The plan would produce $4,646,000 in net benefits annually.

The physiochemical-biological interactive effects of disposal of all the material in the gulf would be similar but to a greater degree than that discussed for the Brookley Expansion plans. These increased quantities of material to be dumped offshore under this plan would also be disposed of in areas 1 and 2 (Figure 12), as with the other plans including gulf disposal. These areas will require further evaluations and study to determine their acceptability. More detailed studies for the plan could be performed in preconstruction planning when more exact quantities of dredged material and definite locations of disposal areas would be known.

Based on available data, general effects of disposal in the open gulf are considered less detrimental than those resulting from disposal within Mobile Bay. However, more energy would be required to implement this plan than any other channel deepening alternative considered, and the land enhancement benefits would be foregone.

**Mitigation Measures.** (Same as the Brookley Expansion Area and Gulf Disposal Plan No. 1 and 2, Modified, except the bridging of US Highway 90, opening of McDuffie fill and establishing 70 acres of wetlands would not be implemented.)
**Implementation Responsibilities.** Responsibility for development of this plan is divided between Federal and non-Federal interests in accordance with established policy and guidelines. The Federal Government may construct or improve channels and harbors to meet the requirements of shipping, while non-Federal interests are responsible for terminal facilities, berthing areas, certain other components, and specified items of local cooperation.

The United States would design and prepare detailed plans, dredge the improved gulf and bay channels and turning and anchorage basins, and maintain the improvement to project dimensions, after Congressional authorization and funding.

Local interests would provide all lands, easements and rights-of-way; all relocations and alterations of utilities; all retaining works and stabilization measures required for disposal of dredged material; and depths in all berthing areas commensurate with those provided in related project areas.

The first cost of general navigation facilities for the 55-foot channel plan considered herein, including navigation aids, would be borne by the United States.

The President, in his June 1978 water policy message to Congress, proposed several changes in cost-sharing for water resources projects to allow states to participate more actively in project implementation decisions. These changes include a cash contribution from benefiting states of 5 percent of first costs of construction assigned to nonvendible project purposes and 10 percent of costs assigned to vendible project purposes.

Application of this policy to this Mobile Harbor plan requires a contribution from the State of Alabama of an estimated $16,880,000 in cash (5 percent of $337,596,000 total estimated project first costs.
assigned to nonvendible project purposes, based on October 1978 price levels). Other items of local cooperation would not be affected by this additional requirement.

Estimated first costs, shown in Table 11, are based upon October 1978 dollar values. This table includes advance engineering and design costs, and the contributions required by local interests.

The presently estimated additional Federal annual maintenance is $1,453,000 which includes annual costs to the U.S. Coast Guard of $4,000 for maintenance of navigation aids. The estimated non-Federal average annual maintenance is $257,000.

CHANNEL WIDENING (Least Environmentally Damaging Plan)

Plan Description. This alternative plan would forego any channel deepening, however, it would consider widening the existing main bay channel 50 feet to reduce traffic delays, provide an additional increment of safety and modify existing dredged disposal techniques to provide for removing all maintenance dredged material to the gulf for disposal. All new work dredged material would also be disposed of in the gulf (see Figure 12).

Evaluation and Assessment. This plan induces no transportation savings from deeper draft vessels but eliminates some traffic delays within the bay and makes a positive environmental contribution to improving circulation in the upper bay and no longer disturbs the bay bottom adjacent to the ship channel by receiving annual maintenance material. The plan reduces the sedimentation of the bay by removing to the gulf approximately 4.2 million cubic yards of dredged maintenance material each year. This volume of maintenance material includes the maintenance of the existing project.
The additional annual charges for this alternative equal $1,395,000. Compared to a reduction in traffic delay costs of approximately $4,884,000, the channel widening plan has a benefit-to-cost ratio of 3.5 and $3,489,000 net benefits.

Model studies indicate that enlargement of the channel is the
dominant cause of salinity changes in the bay. In view of the above,
the less detrimental effects of dredged material disposal, improved safety conditions for ships and retarding the filling of the bay, the Channel Widening Plan is regarded as the least environmentally damaging plan.

**Mitigation Measures.** Mitigation measures for this plan, based on available information, are not warranted; however, there are EQ measures that have previously been addressed as mitigation measures that have positive environmental value that could be included in the Channel Widening Plan.

Studies indicated that along the main channel between a point on the same latitude as the mouth of Dog River to a point about 2 miles to the north, approximately 4.3 million cubic yards of material would have to be removed to eliminate the ridges between the channel and adjacent bay bottom. This material could be placed by hydraulic pipeline dredge into the existing depressions located in the upper bay, thereby reducing the tendency of concentrated low oxygen water developing in the depressions. Preliminary studies indicate this measure would cost approximately $6,000,000 to implement. This equates to an average annual cost of $414,000. In view of the cost, uncertainty of existing impacts and benefits from measures such as this, model studies should be performed to more accurately determine the effects on circulation prior to implementing such measures. These model studies may show that creating openings in the causeway or other measure may achieve more desirable and effective results for less costs.

The establishment of additional oyster beds in Bon Secour Bay is another environmental measure that is considered desirable. However, this too depends on very accurate assessments of any changes to the circulation and resultant salinity variations that might be created by implementing any structural alternative. Model studies could furnish the needed data to investigate this need further.
Implementation Responsibilities. Responsibility for development of this plan is divided between Federal and non-Federal interests in accordance with established policy and guidelines. The Federal Government may construct or improve channels and harbors to meet the requirements of shipping, while non-Federal interests are responsible for terminal facilities, berthing areas, certain other components, and specified items of local cooperation.

The United States would design and prepare detailed plans, dredge the improved gulf and bay channels and turning and anchorage basins, and maintain the improvement to project dimensions, after Congressional authorization and funding.

The first cost of general navigation facilities for the Channel Widening Plan considered herein, including navigation aids, would be borne by the United States.

The President, in his June 1978 water policy message to Congress, proposed several changes in cost-sharing for water resources projects to allow states to participate more actively in project implementation decisions. These changes include a cash contribution from benefiting states of 5 percent of first costs of construction assigned to nonvendible project purposes and 10 percent of costs assigned to vendible project purposes.

Application of this policy to this Mobile Harbor plan requires a contribution from the State of Alabama of an estimated $940,000 in cash (5 percent of $18,798,000 total estimated project first costs assigned to nonvendible project purposes, based on October 1978 price levels). Other items of local cooperation would not be affected by this additional requirement.
Estimated first costs, shown in Table 12, are based upon October 1978 dollar values. This table includes advance engineering and design costs, and the contributions required by local interests.

The presently estimated additional Federal annual maintenance is \$54,000. There is no increase in the non-Federal annual maintenance.

PUBLIC VIEWS

On 31 July 1979 a final public meeting was held to present the results of the study. Notices of the public meeting were furnished the United States Senators and Representatives from the area, Federal and State agencies, city and county authorities, and interested organizations and individuals. General support for the selected plan was received from the U.S. Congressmen, Department of Transportation and Department of Commerce (Maritime Administration). Federal agencies such as the Department of Interior, Environmental Protection Agency and Department of Commerce (National Oceanic and Atmospheric Administration) expressed a general objection to placing dredged material adjacent to the Brookley shoreline and creating a fast land area.

A considerable majority of those represented at the meeting were in favor of the selected plan for Mobile Harbor. However, several environmental groups and local citizens spoke or wrote letters expressing concern or opposition to the selected plan. Concerns included the necessity or desirability of deepening Mobile Ship Channel and the potential environmental degradation of the bay with

particular emphasis on the Brookley Expansion Area. Environmental groups in general feel that if channel enlargement is necessary, then the dredged material should all be transported to an approved disposal site in the Gulf of Mexico.

Appendix 3 contains letters and responses from Federal and State agencies, and concerned local groups and individuals. A transcript of the public meetings was prepared and is available at the Mobile District Office.
COMPARISON OF DETAILED PLANS

The selection of the best plan to solve the problems and meet the needs of the study area results from a comparison of alternative plans. This comparison is based on the effect assessment, the contributions to the four accounts—National Economic Development (NED), Environmental Quality (EQ), Regional Development (RD), and Social Well-Being (SWB)—and responsiveness to stated evaluation criteria.

SYSTEM OF ACCOUNTS

Federal criteria for water resources planning establish the need for an allocation of significant beneficial and adverse effects of considered plans in terms of the four basic accounts—NED, EQ, RD, and SWB. A display of the effects in terms of the system of accounts (SA) is also required.

Contributions of the plans in detail to the four accounts are presented in summary form in Tables 13A through 13E.

The SA displays information concerning the location of beneficial or adverse effects. As a minimum, one region, such as a city or county, and the rest of the nation must be shown. In the Mobile report, three regions are shown for which effects have been identified. They are: (1) the study area, consisting of Mobile and Baldwin Counties and the immediate project area within and adjacent to Mobile Bay; (2) a larger area affected by the project which is further subdivided as the primary tributary area for commodities handled at the port and the Gulf of Mexico, including the Mississippi Sound; and (3) the rest of the nation.
Throughout the display, there will be numerical footnotes and asterisks. The numerical notations refer to information associated with the timing, uncertainty, exclusivity, and actuality of the effect described. The asterisks note items included in those specifically required by Section 122, PL 91-611. Below is an index of the notations.

TIMING
1. Impact is expected to occur prior to or during implementation of the plan.
2. Impact is expected within 15 years following plan implementation.
3. Impact is expected in a longer time frame (15 or more years) following implementation.

UNCERTAINTY
4. The uncertainty associated with the impact is 50% or more.
5. The uncertainty is between 10% and 50%.
6. The uncertainty is less than 10%.

EXCLUSIVITY
7. Overlapping entry; fully monetized in NED account.
8. Overlapping entry; not fully monetized in NED account.

ACTUALITY
9. Impact will occur with implementation.
10. Impact will occur only when specific additional actions are carried out during implementation.
11. Impact will not occur because necessary additional actions are lacking.

<thead>
<tr>
<th>Effects</th>
<th>Study Area</th>
<th>Larger Area</th>
<th>The Nation</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>1. National Economic Development</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>a. Positive</td>
<td>No direct beneficial effects on a local or national scale.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>b. Negative</td>
<td>No direct commitment of local or national resources.</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>2. Environmental Quality</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>a. EQ Enhanced</td>
<td>No enhancement of environmental resources.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>b. EQ Degraded</td>
<td>Disposal of maintenance material from the bay and bar channels would continue to disrupt the benthic communities at the disposal sites. Disposal munus and their possible effects on circulation would continue to persist in the upper bay.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>c. EQ Destroyed</td>
<td>No environmental resources would be irretrievably lost as a result of dredging the bay or bar channels. Utilization of the upper harbor disposal areas would eliminate 135 acres of reestablished prime marshland.</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>3. Social Well-Being</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>a. Beneficial</td>
<td>Health, safety and community well-being would be unaffected; educational, cultural and recreation opportunities would not be influenced.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>b. Adverse</td>
<td>No unfavorable effects.</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>4. Regional Development</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>a. Beneficial</td>
<td>No significant effects on income, employment or economic growth of the region.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>b. Adverse</td>
<td>No unfavorable effects.</td>
<td></td>
<td></td>

</tbody>
</table>

- **Within the immediate planning area**
  - Significantly enhance industrial & port facilities (2,6,10)
  - Opportunity exists for improving circulation in the upper bay below the disposal area and north of the Theodore Channel by discontinuing existing methods of disposing maintenance material alongside the main ship channel.
  - The major factor is the number & type of industry (2,5,10)

- **Within the rest of the study area (SMSA)**

- **Within a larger area affected by the plan (BEA)**
  - Significant effects due to increased port facilities (2,5,10)

- **Within the rest of the nation**
  - Impact will not occur because necessary additional actions are lacking.

**Section 122**

Items required by Sec. 122 & ER 1105-2-105.

COMPARISON OF DETAILED PLANS

The comparisons described in the preceding paragraphs yield the following conclusions regarding the five alternatives under consideration.

- **"No Action."** This plan makes no positive contributions to any account. Therefore, in comparison to the structural alternatives, it foregoes any NFD benefits resulting from navigation savings and any EQ benefits resulting from removing sediments from the upper bay area. Also, because it solves no problems and meets no needs, the plan is not desired by local navigation interests and fails to meet the tests of acceptability.

- **Brookley Expansion Area and Gulf Disposal Plan No. 1, Modified.** This plan addresses the navigation problems, fits the long-range port development goals of the Alabama State Docks Department, and eliminates all future disposal of dredged maintenance material in the bay.

- **Brookley Expansion Area and Gulf Disposal Plan No. 2, Modified, (NED).** This plan contributes mainly to the NED account, and it is superior to all others when compared on the basis of net benefits. The environmental problems described earlier are slightly greater than other structural plans, however, this plan is considered to have general acceptability because it addresses the navigation problems and fits the long-range port development goals of the Alabama State Docks Department.

- **Gulf Disposal Plan No. 1.** Like the Brookley Expansion plans, this plan addresses the navigation problems in that it provides the same channel design. However, this plan does not provide for an area
that can be utilized for future port expansion. The plan addresses the environmental problems of disposal of dredged material in the bay and is considered to have general acceptability.

- **Channel Widening (Least Environmentally Damaging Plan).**

While the other structural alternatives make positive contributions primarily to the NED account, this plan makes a significant contribution to the EQ account. The Channel Widening Plan was retained for further consideration because it had acceptability even though it did not satisfy the planning objectives as well as the other structural alternative.

The benefit/cost ratios of the considered structural plans are exhibited below for comparison.

</tr>
</tbody>
</table>

Comparison of the Brookley Expansion Area and Gulf Disposal Plans No. 1 and 2, Modified, and the Gulf Disposal Plan No. 1 reveals they contribute essentially similar enhancement benefits. The benefits for the Channel Widening Plan were gained entirely from the reduction in traffic delays in the main bay channel.
RATIONALE FOR DESIGNATION OF NED PLAN

Traditional methods for channel modification in Mobile Bay were developed on the basis of economic efficiency and considered open-water disposal of all the dredged disposal material in the bay. A plan such as this would maximize NED efficiency, however, this plan was dropped from consideration since current standards do not consider it a viable or acceptable alternative. The alternative plan that was retained that maximizes NED efficiency is the Brookley Expansion Area and Gulf Disposal Plan No. 2.

RATIONALE FOR DESIGNATION OF LEAST ENVIRONMENTALLY DAMAGING PLAN

The environmental objective of the study was to maintain and enhance EQ. A number of EQ measures have been developed that will have positive contributions to this EQ objective. A plan that would only modify the existing maintenance practice of disposing in open-bay water adjacent to the main bay channel and provide no enlargement to the channel would have a net positive contribution to Mobile Bay and satisfy an EQ objective by enhancing the bay bottom. This plan was further expanded to provide for removing the material from the ridges along the upper reach of the main ship channel, filling low oxygen depressions, establishing oyster beds, nourishing the Dauphin Island beaches, opening the U.S. Highway 90 causeway to improve circulation, regulating flows in the Mobile Delta, and opening the fill connecting McDuffie Island. The above EQ measures were combined with a plan to widen the main bay channel that addressed economic efficiency and safety. It is questionable whether the Channel Widening Plan would result in positive net environmental impacts,
therefore, it is considered the least environmentally damaging alternative.

RATIONALE FOR SELECTED PLAN

Following the foregoing comparison, a selection was made between the structural plans. Considerations which led to the selection of one plan over the other are as follows:

- Although the Channel Widening Plan makes a contribution to the EQ account by the removal of dredged material from the upper bay and places it in a less detrimental gulf disposal area, the plan foregoes all transportation savings from deeper draft vessels by limiting the depth to existing dimensions. Although this plan is economically efficient it does not meet the major port need for deeper channels.

- Disposition of dredged maintenance material in the lower bay appears to have few or no permanent detrimental effects on the bay; however, this disposal technique has received considerable objections from environmental interests.

- Construction of a disposal area in the upper bay not only produces regional economic benefits for land enhancement but provides significant savings in disposal of new work dredged material. The additional cost for implementing the Gulf Disposal Plan is not considered justified.

- A judgement was made that the additional cost for modifying the dredged maintenance material disposal for the existing project would be offset by environmental gains and benefits of the existing
commodity movements. Based on available data, offshore disposal in the area 2 of the Gulf of Mexico was selected as the best disposal site for the existing and future channel maintenance material. This option is the most conservative option to show sound feasibility for selecting a plan of development; however, ongoing Corps of Engineers studies and 404(b) evaluations may indicate open-water bay disposal areas more suitable in view of environmental and economic impacts.
RECOMMENDED PLAN

In view of overall evaluation, design criteria and planning objectives, the plan defined herein as the Brookley Expansion Area and Gulf Disposal Plan No. 1 (Modified) is considered the best plan for implementation. This plan, in combination with other structural endeavors to improve water quality that were identified in the report as requiring additional model studies, will best solve existing problems and meet the needs of the study area.

The recommended plan was analyzed in light of the requirements set forth in Section 150 of the Water Resources Development Act of 1976 (Public Law 94-587) to determine the feasibility of establishing wetland areas by using disposal material. About 70 acres of wetlands will be created for mitigation. The establishment of additional wetlands as provided for in Section 150 is currently being studied under the Mobile Harbor operation and maintenance program.

Fill of any wetland or water areas for expansion of port facilities is environmentally undesirable. Also, the responsibilities outlined in Executive Order 11988 for evaluating potential effects of actions on flood plains were considered in this study; however, there are no practical alternatives to the Brookley area in the upper harbor if significant additional port development areas are to be provided. Consideration of the area adjacent to Brookley Industrial Complex for fill and development is consistent with plans that are supported by the city of Mobile and the Alabama State Docks Department. The area would be adjacent to deeper channels and could be easily connected with existing highway, rail, and intra-harbor cargo transfer facilities. Physically, the area is characterized by submerged and emergent dredged material deposition mounds, borrow
are pulled into the area as the result of the shadowing of river flow by McDuffie Island and remains of the Arlington Pier. Although recent recovery trends have been noted in the area, it continues to have persistently low dissolved oxygen in the borrow depression, and marine life and water quality have been degraded from years of pollution from the Garrows Bend area. During initial dike construction for the Brookley fill resulting turbidities would be unavoidable. However, upon closure of the peripheral dike, all disposal within the area would be controlled and the material permanently contained. Model tests to date do not indicate any significant effects of the Brookley fill on circulation in Mobile Bay although more detailed tests would be conducted before any actual construction would be undertaken.

A southwesterly slant of the southern side of the fill could minimize entrapping effects such as presently exist as the result of McDuffie Island. The Brookley site would be the most beneficial to port and economic development and would represent the least environmental loss when compared to other bay bottom areas within Mobile Bay. The recommended plan would also provide for an opening in the McDuffie Island causeway as a mitigative measure to further enhance water circulation and biological productivity in the Garrows Bend area.

Model tests of overall bay effects of the channel enlargement indicate a slight increase in the average salinity in the northeast quadrant of the bay and a slight reduction in the Bon Secour Bay area. It is unclear at this time whether the changes are the result of more or less freshwater in the respective areas. Further model tests and evaluations of these effects will be a part of any recommendations for enlargement of the Mobile Harbor Channel. In view of the extreme natural fluctuations of Mobile Bay between fresh and saline conditions, assessments of the small variations in the averages have been inconclusive as to whether net impacts may be beneficial or adverse.
Essentially all material from past dredging of navigation channels in Mobile Bay has been deposited in open waters adjacent to the ship channel. Physical buildups have occurred in the upper portion of the bay but little long-term effects are indicated in the lower bay. The effects of these operations on the chemistry of the bay have been the subject of much hypothesis and conjecture. However, little scientific data exist to support any firm conclusions. Regardless of the available data that indicates only minor impacts of estuarine open-water disposal of dredged material, many agencies and other interests advocate deep ocean or gulf disposal of dredged material. Gulf disposal is recommended for most of the new work and all future maintenance for Mobile Harbor, although we have limited data on potential gulf impacts at this time. The data limitations are largely due to the still-emerging criteria for evaluating ocean disposal impacts. However, all appropriate studies would be accomplished before any ocean disposal of new work is initiated. In the interim much of the needed studies and evaluations may be accomplished by our dredged material disposal study for Mississippi Sound and Adjacent Areas. The scope of that study will include an evaluation of the impacts of both ocean and estuarine open-water disposal with either remaining a future option depending upon more detailed study outcomes.

Modification of the US Highway 90 Causeway across Mobile Bay will require additional studies in order to identify this measure as the most cost effective and environmentally desirable method of mitigating the loss of bay bottom taken for the Brookley expansion area.

Overall, many long-term and complex investigations have been performed in connection with our studies for Mobile Harbor. This information indicates that modifications to the recommended plan can be made within the scope of work identified in this study to correct or mitigate environmental damage related to the proposed harbor.
improvements. However, due to the complexity of the affected resources, increasing knowledge of water resource behavior and changing policies and legislation regulating the planning process, additional studies will be required before some of the recommended harbor modifications can be identified in detail.
ENVIRONMENTAL IMPACT STATEMENT
(SUMMARY)

The following is a general summary of the Draft Environmental Impact Statement. The complete document is attached as Appendix 1.

Description of Action. The recommended plan for improvement of Mobile Harbor consists of enlarging the existing channel to provide a depth of 57 feet and a width of 700 feet from the 57-foot depth contour in the Gulf of Mexico for a distance of about 7.4 miles to a point in Mobile Bay near the eastern end of Dauphin Island; enlarging the channel through Mobile Bay to a depth of 55 feet and width of 550 feet for a distance of about 27 miles between the inner end of the gulf entrance channel and a point about 3.6 miles south of the mouth of Mobile River; enlarging the channel into the harbor to provide a depth of 55 feet and a width of 650 feet for a distance of about 4.2 miles to a point 1 mile south of the Interstate Highway 10 Tunnel and providing an anchorage area 500 feet, in addition to the channel width, 55 feet deep and 4,000 feet long on the east side of the main channel and immediately south of a turning basin to be constructed to a 55-foot depth, a 1,500-foot width (including the channel) and 1,500 feet long just south of Little Sand Island. The project would provide for disposal of about 141.2 million cubic yards of new work material as well as all future maintenance material for a 50-year economic life. Approximately 63,400,000 cubic yards of new work material in the upper bay reach would be excavated by hydraulic pipeline dredge and pumped to a diked disposal area in the vicinity of the Brookley waterfront. Construction of the lower bay reach would involve removal of about 58,700,000 cubic yards of material by hydraulic dredge utilizing dump scows and tow boats to transport the dredged material to a gulf disposal area, the location of which to be
designated by the Environmental Protection Agency in accordance with the 11 January 1977 Ocean Dumping Criteria, developed pursuant to the Marine Protection, Research, and Sanctuaries Act of 1972, PL 92-534. Maintenance of the upper and lower bay channels would also be by hydraulic dredge and transported by dump scows offshore. New work, approximately 19,100,000 cubic yards, and maintenance material from the bar channel would be excavated by hopper dredge and disposed at a gulf site. The benefit-to-cost ratio for the project is 1.5 to 1.

**Environmental Impacts.** Evaluated accomplishments that would result from implementation of the recommended plan are direct transportation savings through increased use of larger, more economical vessels, and land enhancement from fast land created adjacent to the Brookley Industrial Complex. In addition, supplemental benefits creditable to improving the harbor channel would result from elimination of lost vessel time due to constrained traffic in the channels. Environmental impacts of the proposed project were evaluated in accordance with requirements of Section 404, PL 92-500, and other applicable laws and guidelines. Primary impacts would be associated with channel construction and subsequent maintenance dredging operations; construction and stabilization of the expansion area in the upper bay; and offshore disposal of dredged material. Secondary impacts would result from the enhanced economic development of the area.

Unavoidable adverse impacts associated with the project would arise from the dredging and disposal operations which would destroy some benthic populations, cause a minor release of pollutational constituents, increase turbidity, and result in a physical loss of some bay bottom habitat and recreational/fisheries areas. There are also other adverse impacts that can be avoided only if remedial measures
can be established. These are associated with modifications to overall circulation and salinity patterns in the bay caused by channel construction and sites of historical interest, if any, located within the channel alignment and disposal areas. Secondary impacts of the project would include higher levels of noise, water, and air pollution related to increased economic development of the area.

Alternatives. Along with a "No-Action" Plan, alternatives include consideration of changes in the widths and depths of the existing channels and various methods of excavation and disposal of dredged material. Dredged material disposal options include: construct island and fill areas in upper and lower Mobile Bay; open-water disposal in the bay and/or gulf; upland disposal; recycle material off existing disposal sites; and shoreline nourishment to abate erosion.

CONCLUSIONS

After carefully considering all technical information and public views, and with particular reference to the economic, environmental, and social well-being considerations, the plan recommended herein is considered to be in the best public interest. The identified needs and studies to date are sufficient to proceed with the selected plan in this report as a framework for future development of Mobile Harbor, contingent upon the additional studies identified. Updated benefit and cost data for the recommended plan is provided as an attachment to the Summary Report.

RECOMMENDATIONS

It is recommended that the existing Federal navigation project for Mobile Harbor, Alabama, be modified, subject to such modifications as the Chief of Engineers may deem appropriate, to provide for:
- Deepening and widening the gulf entrance channel to 57 by 700 feet,

- Deepening and widening the main ship channel to 55 by 550 feet in Mobile Bay, except for the upper 3.6 miles which require a width of 650 feet,

- Deepening the Mobile River channel to 55 feet to a point about 1 mile below the Interstate 10 highway tunnels, and

- Constructing turning and anchorage basins near the upper end of the main ship channel.

The recommended plan further provides for related improvements including justified mitigation measures in accordance with the selected plan in this report. The work may be accomplished in separable increments as determined feasible by the Chief of Engineers, in that accordingly, written agreements required by Section 221, PL 91-611, may be accepted for preceding independently with each such increment.

This recommendation is made with the provision that, prior to the commencement of construction, local interests will, in addition to the general requirements of law for these types of projects, agree to comply with the following requirements:

a. Provide without cost to the United States all lands, easements, and rights-of-way necessary for construction and maintenance of the project and for aids to navigation upon the request of the Chief of Engineers, including suitable areas determined by the Chief of Engineers to be required in the general public interest for initial and subsequent disposal of dredged material, and including
necessary retaining dikes, wiers, bulkheads, and embankments therefor, or the costs of such retaining works;

b. Hold and save the United States free from damages due to the construction and maintenance of the project, not including damages due to the fault or negligence of the United States or its contractors;

c. Accomplish without cost to the United States all alterations and relocations of buildings, transportation facilities, storm drains, utilities, and other structures and improvements necessary for project purposes.

d. Provide and maintain without cost to the United States vessel berthing areas and local access channels;

e. Prohibit erection of any structure within 175 feet of the project channel as authorized;

f. Provide and maintain without cost to the United States adequate public terminal and transfer facilities open to all on equal terms;

g. Provide a cash contribution based on the final first cost allocated to special local benefits deriving from land enhancement due to landfill; and

h. Fulfill the requirements of non-Federal cooperation as specified in the terms of conditions of the Uniform Relocation Assistance and Real Property Acquisition Policy Act of 1970 (PL 91-646) approved 2 January 1971.
Application of the President's June 1978 water policy to the Mobile Harbor project requires a contribution from the State of Alabama of an estimated $16,904,000 in cash (5 percent of $338,072,000 total estimated project first costs assigned to nonvendible project purposes based on August 1980 price levels). Other items of local cooperation would not be affected by this additional requirement.

ROBERT H. RYAN
Colonel, EN
District Engineer
MOBILE HARBOR, ALABAMA

BENEFIT AND COST UPDATE

The navigation benefits and project costs shown in the summary and technical appendix are based on October 1978 data. This attachment updates the benefits and costs to August 1980.

BENEFITS

The procedure for updating these benefits is based on an unadopted uniform method of updating benefits for deep draft navigation projects, as published in EC 1105-2-80 dated 16 May 1977. The economic indicators are: 40% for skilled labor and 30% for construction, as published in Engineering News-Record, and 30% for transportation, as published in Survey of Current Business. A further adjustment indicator was applied to reflect changes in the price of fuel. Based on dry bulk carriers data and costs submitted by OCE in 1979, fuel costs represent about 24% of the vessels' total annual operating costs. The remainder or 76% was proportioned to the other three indicators based on their relative position. The results of these adjustments are as follows:

<table>
<thead>
<tr>
<th>Indicator</th>
<th>Skilled labor</th>
<th>Construction</th>
<th>Transportation</th>
<th>Fuel costs</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>40%</td>
<td>76%</td>
<td>30%</td>
<td>24%</td>
</tr>
<tr>

<td>30%</td>
<td>30%</td>
<td>or</td>
<td>23%</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The 1 October 1978 benefits as shown in the report are based on vessel costs effective 1 January 1977. Since vessel cost "with" and "without" project are based on the same vessels, but being more fully
loaded, the benefits are directly associated with the relative costs; consequently, the benefits only are updated. The following procedure was used to determine the increase factor:

### Update Factors

**COSTS**

The first costs given herein are estimated for the selected plan and the Gulf Disposal Plan No. 1 as described in the summary report and in Section E of Appendix 5. Costs are based upon August 1980 dollar values. The advance engineering and design costs, maintenance during construction and interest during construction reflect compressing the post-authorization schedule on plate F-1 in Section F of Appendix 5. A schedule was coordinated with South Atlantic Division staff that shows Phase I and Phase II AE&D studies complete in four years, construction beginning one year following the approval of Phase II GDH and construction taking four and one-half years.

The contributions required by local interests are based on 100% of the cost allocated for land enhancement of the Brookley expansion area, a share of the mitigation costs based on the percent of local project costs to the total cost, and 5% of total estimated project first costs.

Annual charges are based on August 1980 dollars, an interest rate of 7 3/8% and an economic period of analysis of 50 years (1995-2044). A detail development of the costs is presented in the following tables:

ENVIRONMENTAL IMPACT STATEMENT

MOBILE HARBOR
CHANNEL IMPROVEMENTS
MOBILE COUNTY, ALABAMA

Prepared by
US Army Engineer District, Mobile
Mobile, Alabama
October 1980
SUMMARY

Mobile Harbor Channel Improvements
Mobile County, Alabama

[X] Final Environmental Statement

[ ] Draft

Responsible Office: U. S. Army Engineer District, Mobile
P. O. Box 2288
Mobile, Alabama 36628
Telephone: (205) 690-2511

1. Name of Action: ( ) Administrative (X) Legislative

2. Description of Action: The proposed plan for improvement of Mobile Harbor consists of enlarging the existing channel to provide a depth of 57 feet and a width of 700 feet from the 57-foot depth contour in the Gulf of Mexico for a distance of about 7.4 miles to a point in Mobile Bay near the eastern end of Dauphin Island; enlarging the channel through Mobile Bay to a depth of 55 feet and width of 580 feet for a distance of about 27 miles between the inner end of the gulf entrance channel and a point about 3.6 miles south of the mouth of Mobile River; enlarging the channel into the harbor to provide a depth of 55 feet and a width of 650 feet for a distance of about 4.2 miles to a point 1 mile south of the Interstate Highway 10 tunnel and providing an anchorage area 500 feet, in addition to the channel width, 55 feet deep and 4,000 feet long on the east side of the main channel and immediately south of a turning basin to be constructed to a 55-foot depth, a 1,500-foot width (including the channel) and 1,500 feet long just south of Little Sand Island. The project would provide for disposal of about 141.2 million cubic yards of new work material as well as all future maintenance material for a 50 year economic life. Approximately 63,400,000 cubic yards of new work material in the upper bay reach would be excavated by hydraulic pipeline dredge and pumped to a diked disposal area in the vicinity of the Brookley waterfront. Construction of the lower bay reach would involve removal of about 58,700,000 cubic yards of material by hydraulic dredge utilizing dump scows and tow boats to transport the dredged material to a gulf disposal area, the location of which to be determined by the Environmental Protection Agency. Maintenance of the upper and lower bay channels would also be by hydraulic dredge and transported by dump scows offshore. New work, approximately 19,100,000 cubic yards, and maintenance material from the bar channel would be excavated by hopper dredge and disposed at a gulf site. The benefit to cost ratio for the project is 1.6 to 1.
3.a. **Environmental Impacts:** Evaluated accomplishments that would result from implementation of the proposed project are direct transportation savings through increased use of larger, more economical vessels, and land enhancement from fast land created adjacent to the Brookley Industrial Complex. In addition, supplemental benefits creditable to improving the harbor channel would result from elimination of lost vessel time due to constrained traffic in the channels. Environmental impacts of the proposed project were evaluated in accordance with requirements of Section 404, PL 92-500, and other applicable laws and guidelines. Primary impacts would be associated with channel construction and subsequent maintenance dredging operations; construction and stabilization of the expansion area in the upper bay; and offshore disposal of dredged material. Secondary impacts would result from the enhanced economic development of the area.

b. Unavoidable adverse impacts associated with the project would arise from the dredging and disposal operations which would destroy some benthic populations, cause a minor release of pollutional constituents, increase turbidity, and result in a physical loss of some bay bottom habitat and recreational/fisheries areas. There are also other adverse impacts that can be avoided only if remedial measures can be established. These are associated with modifications to overall circulation and salinity patterns in the bay caused by channel construction, and sites of historical interest, if any, located within the channel alignment and disposal areas. Secondary impacts of the project would include higher levels of noise, water, and air pollution related to increased economic development of the area.

4. **Alternatives:** Along with a no action plan, alternatives include consideration of changes in the widths and depths of the existing channels and various methods of excavation and disposal of dredged material. Dredged material disposal options include: construct island and fill areas in upper and lower Mobile Bay; open water disposal in the bay and/or gulf; upland disposal; recycle material off existing disposal sites; and shoreline nourishment to abate erosion. Environmental improvement measures to be considered further in connection with navigation improvements include: restore tidal action in Chacaloochee and Polecot Bays; establish oyster beds in Bon Secour Bay; improve water circulation in Mobile Bay by creating openings in ridges paralleling the channel from Dog River to Mobile River; fill depressions which exist in Mobile Bay; establish a recycle plan to remove material from existing Blakely and Pinto Island disposal areas; and evaluate the feasibility of establishing wetland areas.

ATTACHMENT 1 Economic Data
1.01 PROJECT DESCRIPTION. The proposed plan for improvements to Mobile Harbor consists of enlarging the existing channel to provide a depth of 57 feet and a width of 700 feet from the 57-foot depth contour in the Gulf of Mexico for a distance of about 7.4 miles to a point in Mobile Bay near the eastern end of Dauphin Island; enlarging the channel through Mobile Bay to a depth of 55 feet and width of 550 feet for a distance of about 27 miles between the inner end of the gulf entrance channel and a point about 3.6 miles south of the mouth of Mobile River; enlarging the channel into the harbor to provide a depth of 55 feet and a width of 650 feet for a distance of about 4.2 miles to a point 1 mile south of the Interstate Highway 10 tunnel and providing an anchorage area 500 feet, in addition to the channel width, 55 feet deep and 4,000 feet long on the east side of the main channel and immediately south of a turning basin to be constructed to a 55-foot depth, a 1,500-foot width (including the channel) and 1,500 feet long just south of Little Sand Island. The total length of the improved channel would be 38.6 miles. A general map of the proposed project is shown as Figure 1.

1.02 The project would provide for disposal of about 141.2 million cubic yards of new work material as well as all future maintenance material for a 50 year economic life. Approximately 63,400,000 cubic yards of new work material in the upper bay reach would be excavated by hydraulic pipeline dredge and pumped to a diked disposal area in the vicinity of the Brookley waterfront. Construction of the lower bay reach would involve removal of about 58,700,000 cubic yards of material by hydraulic dredge utilizing dump scows and tow boats to transport the dredged material to a gulf disposal area, the location of which to be determined by the Environmental Protection Agency. Maintenance of the upper and lower bay channels would also be by hydraulic dredge and transported by dump scows offshore. New work, approximately 19,100,000 cubic yards, and maintenance material from the bar channel would be excavated by hopper dredge and disposed at a gulf site.

1.03 Post-authorization environmental studies under the recommended plan would include further model tests, cultural resources surveys, refinement of a wetlands establishment program, a bay usage investigation, offshore disposal site evaluations, and further evaluation of alternative mitigation features. In addition to the wetlands establishment program, mitigation alternatives include (1) restore tidal action in Chačaloocché and Polecat Bays and Garrows Bend, (2) establish oyster beds in Bon Secour Bay, (3) improve water circulation in Mobile Bay by...
creating openings in ridges paralleling the channel from Dog River to Mobile River, (4) fill depressions which exist in Mobile Bay, and (5) establish a recycle plan to remove material from existing Blakeley and Pinto Island disposal areas. As discussed in section 6, items listed above as number 1 could be implemented without further model studies. Further coordination with Federal, State, and local agencies, citizen groups and interested parties would be included with the post-authorization studies.

1.04 The proposed plan represents a comprehensive guide for development of Mobile Harbor. In order to maintain efficiency and safety, separable features could be implemented early at the existing authorized depth of 40 feet. These include channel widening in the upper bay, a turning and anchorage area at the head of the bay, a passing lane in the central area of the bay, and mitigating features to improve water circulation in Chacaloochee Bay and Garrows Bend. Incremental construction of the project would be analyzed further during post-authorization studies.

1.05 The survey studies for Mobile Harbor have been developed in compliance with a resolution adopted 24 June 1965 by the Public Works Committee, United States House of Representatives directing that studies be made to determine whether the existing project should be modified. Due to a request by local interest early studies addressed evaluation and preparation of an interim survey report on the now authorized Theodore Ship Channel project. The proposed project was formulated consistent with the Water Resource Council Principles and Standards (P&S).

1.06 The existing project for Mobile Harbor was authorized by Section 104 of the River and Harbor Act of 3 September 1954 (House Document 74, 83rd Cong., 1st Session), and previous acts. Authorized dimensions provide a 42-by 600-foot channel about 1.5 miles long across Mobile Bar; a 40-by 400-foot channel in Mobile Bay to the mouth of Mobile River; a 40-foot channel in Mobile River to the Cochrane Bridge, varying in width from 500 to 775 feet; and several branch channels turning basins and anchorages all of which are described in detail in the environmental impact statement for operation and maintenance of the project.

1.07 Maintenance of the 41.7 miles of navigation channels within the existing Harbor Project system requires several different operational methods, depending upon the location of the specific channel segment. The Bar Channel is maintained with a hopper dredge, with deposit of the dredged material in the open gulf in an approximately 4.4 square mile disposal area located just south of Dauphin Island. The disposal area has interim approval by the Environmental Protection Agency (EPA) as an ocean dumping site. The Bay Channel is maintained with a hydraulic pipeline dredge and the dredged material is deposited in open water on both sides of the channel. Fifteen disposal sites paralleling the channel occupy approximately 20,090 acres of bay bottom and are almost continuous along both sides of the channel. The Mobile River segment of the harbor project is maintained using a hydraulic pipeline dredge with disposal of the dredged material in diked-land areas known as Blakely Island and Pinto Island.
1.08 Evaluated accomplishments that would result from implementation of the proposed project are direct transportation savings through increased use of larger, more economical vessels, and land enhancement from fast land created adjacent to the Brookley Industrial Complex. In addition supplemental benefits creditable to improving the harbor channel would result from elimination of lost vessel time due to constrained traffic in the channels. As shown on Attachment 1 the initial Federal cost of the proposed project is $295,494,000. Non-Federal initial cost is $42,578,000. The average annual benefits to be derived from the project are estimated at $32,613,000, while the total average annual charges are estimated at $32,613,000. The benefit to cost ratio is 1.6 to 1.0.

1.09 Construction of the proposed project could be accomplished in about seven years, utilizing one 30 inch hydraulic dredge for the upper bay, one modified 27 inch hydraulic dredge in the lower bay reach, and for about three years, one hopper dredge for the entrance channel. The 27 inch pipeline dredge would be modified by lowering the pump on the dredge ladder near the cutterhead to obtain greater densities in the dredge effluent and better economies from the barging operation. Also the dredge would be modified to discharge into dump scows at a production rate of 2,500 cubic yards per hour in situ. It is estimated a fleet of 8 tow boats and 16 dump scows would be required to transport the new work dredged material from the lower bay channel to a gulf disposal site without delaying dredging operations.

1.10 The completed channels would have side slopes of one vertical on five horizontal. Initial dredging would provide for an allowance of two feet overdepth required for advance maintenance plus two feet of allowable overdepth to compensate for inaccuracies in the dredging process. Most of the material to be excavated is composed of gray clay of high plasticity (fat clay) with occasional lenses of gray sandy clays and silty sands. Sand can be found in the upper third of the bay to a point about 6.5 miles south of the mouth of Mobile River. It is expected that material dredged from the Bar Channel would also be sandy.

1.11 As shown on Figure 2 the sandy new work material from the upper third of the bay would be used to construct the dikes and fill approximately 61 percent of the Brookley expansion area. This would provide 1,047 acres of fast land to an elevation approximately 17.5 feet above mean low water. The remainder of the fill area would accommodate approximately 24 million cubic yards of new work material (clay) from the next 6 miles of channel down to the intersection of the Theodore channel. Further details on the design of the disposal areas are contained in Section E, of the Technical Report (Appendix 5).

1.12 After a period of consolidation and stabilization the dikes would be shaped up and provided with an appropriate covering to protect against erosive wave action. Those areas exposed to high energy waves would be armored with riprap. The dike slopes above mean high water and the wave wash area would be protected with grass. Wetlands would be established on the southern end of the disposal area to mitigate the loss of about 70 acres of marsh presently growing on the Brookley shoreline.

Appendix 1
Results of engineering and environmental studies currently being conducted in connection with construction of the disposal island for the Theodore Ship Channel would be used in establishing a plan to minimize adverse environmental effects during construction of the Brookley expansion area. Also, a study of dredging in Mississippi Sound and adjacent areas has been initiated by the Mobile District Corps of Engineers as a result of Congressional resolutions of 1977. The main purpose of the study is to determine whether the present and proposed dredged material disposal methods for maintenance and construction of the various projects in Mississippi Sound and Mobile Bay, should be modified in any way, in the interest of economic efficiency and environmental quality. The resolutions request an investigation of various dredging techniques and the possibility of developing a coordinated program for the region, with appropriate consideration of ecological factors. The study is scheduled to be completed in 1982. Further planning for improvements to Mobile Harbor will be developed consistent with the Mississippi Sound study.

Existing Federal projects involving maintenance dredging in proximity to the proposed project include: Mobile Harbor, Dauphin Island Bay, Dog River, Fowl River, Fly Creek, Bon Secour River, and the Gulf Intracoastal Waterway. Environmental impact statements (EIS) for operation and maintenance of these Federal projects have been completed. The Theodore Ship Channel project, developed from survey scope investigations for navigation improvements to Mobile Harbor, is in the initial stages of construction and is described in an EIS.

Non-Federal activities in the bay and tributaries include shell dredging, exploratory oil drilling, expansion of the McDuffie coal handling facility, lengthening of the Chickasaw Creek Channel, construction of a private coal handling facility, and a multitude of minor activities such as pier and bulkhead work. All of these activities have involved Corps of Engineers Regulatory permits. Other activities such as large scale land development for both residential and industrial sites are also in progress about the bay's periphery.
2.01 ENVIRONMENTAL SETTING WITHOUT THE PROJECT. The Mobile Bay region consists of Mobile and Baldwin Counties which are the only Alabama counties bordering the Gulf of Mexico. This region of over 400,000 people is rural in character except in the vicinity of Mobile. The city serves as a major wholesaling and to a lesser extent retailing center for much of southern Alabama and adjacent sections of Mississippi and Florida. The abundant resources of the nearby forest has made paper and allied lumber and wood products two of the most important manufacturing industries in the region. Waterborne shipping is another important aspect of commerce and the port of Mobile presently ranks 12th among U.S. ports in total volume handled.

2.02 Transportation Facilities. The dominant feature of the region is Mobile Bay which stretches about 30 miles from the mouths of the Mobile and Tensaw Rivers in the north of Pelican Point and Fort Morgan to the south, which mark the ends to the Gulf of Mexico. The bay is shallow, averaging only 9.7 feet deep, but it is crossed from the north to the south by the existing 40-foot deep ship channel from the gulf to the port of Mobile and east to west in the southern part of the bay by the 12-foot deep Intracoastal Waterway. Other smaller channels around the periphery of the bay include; Dog River, Fowl River, Fly Creek, Dauphin Island Bay, and Bon Secour River.

2.03 A well-developed system of transportation serves the Mobile area via an integrated network of highway, air, rail, and waterway transportation facilities. These facilities are constituted by six U.S. highways, two Interstate routes, two airports, four railroads, and 55 common freight carriers. The area is also served by a well-developed system of waterways including the coastal ones discussed in paragraph 2.02 and an extensive inland navigation system. Barge traffic in the area is accommodated by the Mobile-Tombigbee-Black Warrior River system, the Mobile-Alabama-Coosa River system, and the Gulf Intracoastal Waterway. The Tennessee-Tombigbee River project which is now under construction will connect a 16,000-mile inland waterway system located in 23 states with the Gulf of Mexico at the port of Mobile.

2.04 There are 108 piers, wharfs, and docks that serve the Mobile Harbor, including dry bulk and coal terminals, a public grain elevator, marine bulk handling and storage, numerous private storage/handling facilities and docking facilities to accommodate extensive local, national and international transportation needs, totaling 32.5 million tons of commerce in 1975. There were 2,800 persons employed in water transportation and transportation services which were directly related to port and waterway activities; 18,000 other manufacturing employees were dependent upon the port and related waterways in 1974, grossing 92.3 and 223.1 million payrolls respectively in 1976 dollars.
2.05 **Population and Economy.** Both Mobile and Baldwin Counties are experiencing rapid population and, consequently, urban growth. The 1976 estimated population of Mobile and Baldwin Counties was 416,600 persons. Although, Mobile County's population is approximately 5 times larger than Baldwin County, both counties are experiencing very rapid growth in population. Baldwin County's overall population increased 17% during the period 1970-76, while Mobile County's growth was 9.4%. The scheduled completion of Interstate 65 across the northern tier of the two counties, in combination with the already completed Interstate 10, has the potential of opening up large tracts of land for residential and industrial development within the area.

2.06 A survey by the South Alabama Regional Planning Commission in 1975 has indicated that a total of 117,600 people were employed in Mobile County and 17,700 in Baldwin County. The majority of these workers were employed in manufacturing and wholesale and retail trade components. Data from the Bureau of Economic Analysis up through 1975 shows a per capita income for Mobile County of $4,770, with Baldwin County running about $250 per annum lower. However, personal income in Baldwin County is rising at a more rapid rate than that of Mobile County. Largest increases have been in nonfarm personal income.

2.07 **Cultural Resources.** Mobile Bay's location and the area's mild climate have contributed greatly to the region's long and varied history. The bay has been the site of considerable navigation activity since the French arrival in 1699. Approximately 17 identified wrecks, ballast dumps or obstructions have been reported on Mobile Bay navigation charts from 1850 to 1976. Each of these are potential significant cultural resources. Additional data can be found in Section B of Appendix 5.

2.08 **Bay Environment.** The Mobile Bay estuarine system occupies 466 square miles including the Mobile River Delta, and it is the northern most estuary interfacing with the Gulf of Mexico (Crance, 1971). The third largest run-off volume in the continental United States (73,077 cfs annual average) enters Mobile Bay from the drainage area covering 43,560 square miles (Ryan, 1969; Chermol, 1974). The range of recorded discharge has been from a maximum of 59,000 cubic feet per second (cfs) to a minimum of about 5,100 cfs (U.S. Army Corps of Engineers, 1975).

2.09 Mobile Bay is 30 miles in length (not including 12.6 miles of delta) and has an average width of 10.8 miles (Tanner, 1970). Within the overall estuarine zone, including the lower Mobile delta, are 6,244 acres of tidal marsh, 12,000 acres of fresh water lakes, 15,127 acres of bayous, rivers, and connecting bays and 249,343 acres in the bay itself. The general characteristics of the Mobile Bay system (circulation, current, salinity, density layers, etc.) reflect a situation which fluctuates seasonally while being greatly influenced by variable volume of stream discharge, wind, and tidal conditions. intermittently, perhaps daily, each of these variables will have a dominant influence on the hydrologic characteristics of the estuary.
2.10 The estuary has a tidal cycle which is diurnal and ranges from 1.5 feet at the head of the bay to 1.2 feet at the entrance. A weighted mean tidal height of the bay, 1.4 feet, and the surface area of the bay produce a tidal prism of 330,575-acre feet. The flushing time during relatively low river inflow conditions of 12,262 cfs is between 45 and 54 days (Austin, 1954).

2.11 Salinities in Mobile Bay change rapidly and over a wide range from 0 to 35 parts per thousand (o/oo). Major fluctuations in river discharge have an immediate effect upon salinity in all parts of the bay, but if short-lived, the effects are usually expressed only in the surface portions of the water column. As a result, conditions in the bay represent a wide range of mixed or stratified salinity conditions. Mixing between the surface and bottom water layers of the bay is not yet well studied. Factors that have altered natural circulation and salinity patterns within the bay include construction of land filled causeways and disposal of dredged material along the deep navigation channels in the upper third of the bay (Chermolk, 1974; U.S. Army Corps of Engineers, 1977).

2.12 Although Mobile Bay has been referred to as a graben by some experts, only one fault has been located. It therefore seems best to assume that it is the drowned mouth of a river valley. As such, it is rapidly filling with sediment. Ryan (1969) has calculated an annual average of 4.7 million tons of suspended sediment and an unknown quantity of bedload being transported annually into the estuary. He has also calculated a bay-wide sedimentation rate of approximately 22 inches during the past century from bathymetric changes in the bay. The bay-wide sedimentation rate of 22 inches per century translates into a quantity approaching 8,000,000 cubic yards, annually.

2.13 Several upland communities are found in the Mobile and Baldwin County area. The four dominant communities are the longleaf pine-oaks community, pine savannah community, bay forest community, and the large floodplain forest community of the Mobile River delta. These natural communities have been removed or altered considerably by man's activities in the area. Additional discussion can be found in paragraph 66 through 70 in Section B of the Survey Report.

2.14 Three general types of wetland communities are found in Mobile and Baldwin Counties. These are fresh water marshes, low salinity brackish marshes, and high salinity salt marshes. All of these marshes receive some tidal influence. The total acreages of wetland habitat within Alabama coastal zone varies widely depending on the author. Estimates have ranged as high as 34,614 acres by Crance in 1971 to 27,346 acres by Vittor and Stout in 1975. Although the latter work has numerous site specific errors, it has taken the most accurate determination of wetland acreage within the Alabama coastal zone. Much of this total acreage occurs in Mobile Bay and Mobile delta. For example, the bay and delta contain 43% of the 2,330 acres of salt marsh available within the coastal zone and 63.4% of the 11,231 acres of fresh-mixed marsh. The bulk of the bay salt marsh is associated with Deer,
Fowl, and Dog Rivers. Brackish to saline species are normally associated with these areas. In the southern part of the bay, marshes are found at Little Point Clear on the north side of Fort Morgan Peninsula, the east end of Dauphin Island and Oyster Bay. Here a peripheral border of Spartina alterniflora grades into almost pure stands of Juncus roemerianus. Higher areas may be characterized by Spartina patens, *Fimbristylis* sp., *Spartina cynosuroides*, *Phragmites communis*, and *Morrichia frutescens*.

2.15 Phytoplankton, zooplankton, and benthic sea grass communities within the bay have been poorly investigated. Such findings as do exist are summarized in Section B of Appendix 5.

2.16 A total of 233 species of fish, representing 173 genera and 80 families, have been documented as occurring in the Mobile Bay area (Swingle, 1971). Eight species were found exclusively in the Mobile Ship Channel. Swingle indicated that the total number of species in the ship channel was higher than that in the adjacent areas in the bay since the high salinity water is conducive to the existence of many of the offshore gulf species.

2.17 Commercial Fisheries. Swingle (1976) stated that 100 species of fish and 11 species of invertebrates are classified as commercial species in Alabama. Most of the seafood is landed in Mobile County at Bayou la Batre which ranked as the 10th port in the nation in the value of seafood landed during the past few years. Commercial landings have increased from about 8 million pounds in 1961 to 30 million pounds in 1978 while showing an increase in dockside value to over $35 million annually. The primary commercial species include striped mullet, Atlantic croaker, kingfish, flounder, shrimp, and oysters. Additional discussion of the trends in the commercial fisheries in Mobile Bay can be found in Section B of Appendix 5.

2.18 Endangered and Threatened Species. The U.S. Department of Interior Fish and Wildlife Service includes in their list 6 mammals, 8 birds, and 4 reptiles that may occur in south Mobile County. However, only the following species have actually been reported from the project area within the last several decades. These are the Florida panther, finback whale, sperm whale, perigrine falcon, brown pelican, Bachmans warbler, ivorybill woodpecker, red cockaded woodpecker, American alligator, Atlantic Ridley sea turtle, hawksbill turtle, and leatherback turtle. Additional discussion can be found in Section B of Appendix 5.

2.19 Offshore Habitat. Data on the offshore benthic habitats are limited for Alabama waters. However, the samples that have been taken indicate that shoreward of the 10-fathom curve the benthic community is richer off Perdido Bay than it is off of Dauphin Island. This probably results from the sediment type which influences the abundance of the macroinfrauna. Smaller numbers of organisms were found in fine sand and clay substrates, but the individual size of each organisms was larger. There is some evidence which suggests a high degree of annual variation within the offshore benthos.
2.20 **Air Quality.** Air pollution exists in Mobile County to the point of violating ambient air quality standards for photochemical oxidants and particulates. The entire county of Mobile is a non-attainment area for photochemical oxidants, that is ozone, and one sub-county area is non-attainment for total suspended particulates. The "downtown area" of Mobile violates the primary total suspended particulates standards. Photochemical oxidants are the product of a complex series of chemical reactions involving oxides of nitrogen, hydrocarbons, and sunlight. A significant portion of the photochemical oxidants with Mobile County are transported from other areas by wind. Within Mobile County, the main source of hydrocarbons is automobile exhaust and petroleum handling operations; the main source of oxides of nitrogen are automobile exhaust and other combustion sources. Additional coverage of air quality can be found in Section B of Appendix 5.

2.21 **Water Quality.** Since the bay is so large, individual pollution sources have little effect on the overall water quality of the bay, except in highly localized areas. Nonetheless, Mobile Bay has been subject to a slow but steady degradation over the years. In some areas, notably Garrow's Bend, there is evidence that this trend has been reversed as the municipalities and industries discharging into the bay have implemented proper treatment methodologies. The most wideranging and serious pollution impact has been the closing of oyster reefs for harvesting. Over 72,000 acres in the northern section of the bay have been permanently closed to the harvest of shellfish because of high coliform levels. Localized severe degradation of water quality has been documented in Chickasaw Creek, Three Mile Creek, and Dog River. An overall comprehensive planning document of the area's water quality has been recently completed by the South Alabama Regional Planning Commission (SARPC, 1978). Although this plan is still under review and has not been approved by the Environmental Protection Agency, specific recommendations have been made to achieve the greatest improvement of water quality of the least expenditure of funds. A total of $582 million would be required for planned implementation through the year 2000.

2.22 The waters of Mobile Bay are classified for a variety of uses by the Alabama Water Improvement Commission according to their existing water quality standards. In general, water quality improves with distance from the Mobile urban center. Most of the bay, including Bon Secour Bay is classified for swimming and fish and wildlife. About two-thirds of the bay is classified for shellfish harvesting in addition to swimming, fish and wildlife, while the northwestern corner of the bay is classified for fish and wildlife.
2.23 Recreation. The coastal area of Alabama offers a wide variety of recreational opportunities to residents and tourists. Because of the abundance of sunshine and water in coastal Alabama, recreation generally means outdoor activities such as fishing, boating, swimming, hiking, hunting, and camping. Native wildlife provides recreation for sport fishermen, waterfowl hunter, and the naturalist. Also, interesting historical sites, public parks, and excellent beaches are located along the shores. A major portion of the Mobile delta has been considered as a national wildlife refuge on two different occasions, 1964 and 1974. Although the refuge status has not been attained, the area has been included in the National Registry of Natural Landmarks. An additional study is presently underway by the National Park Service to determine the area's capability of being included within the Federal system of parks.

2.24 Recreation is also an important income producing industry within the state. For example, visitors to Gulf Shores in 1976 spent $5 million for food and lodging. This of course does not include receipts for gas, boat rentals, and other items used by vacationers. Data concerning other local expenditures are not available. However, travelers and tourists in Alabama spent more than $1 billion in 1977 and a significant portion of this amount was spent in coastal Alabama.
3.01 Relationship of the Proposed Project to Land Use Plans. The proposed project would provide additional land for port expansion in an area compatible with future projects of the "Regional Land Development and Policies Plan," 1977, developed by the South Alabama Regional Planning Commission with participation from other local land use affiliated groups. By letter of 25 September 1979 (Appendix 3) the South Alabama Regional Planning Commission indicates that the proposed plan is consistent with current area-wide plans, programs, and objectives.

3.02 As a result of Federal and State legislation, Alabama is developing a coastal zone management program under the direction of the Coastal Area Board. By letter of 12 May 1980 (Appendix 3), the Coastal Area Board concludes that the recommended plan and all alternatives are consistent with their management program, provided that biological resources are protected to the maximum extent practicable and appropriate mitigation measures are implemented.
4.01 THE PROBABLE IMPACT OF THE PROPOSED ACTION ON THE ENVIRONMENT. Primary environmental impacts of the proposed project would be associated with:
(1) channel construction and subsequent maintenance dredging operations,
(2) construction and stabilization of the expansion area in the upper bay,
and (3) offshore disposal of dredged material. Secondary impacts of the project would result from the enhanced economic development of the area.

4.02 Impacts of Channel Construction. About 700 acres of bay bottom and 520 acres of near shore bottom would be committed to the enlarged channel in addition to the areas in the existing channels. From a productivity viewpoint this impact is considered adverse since benthic productivity in the area committed to the enlarged channel is expected to diminish by approximately 80 percent. However, Swingle (1977) and others have indicated that the existing ship channel supports a more diverse fish fauna than the balance of the bay. Also, deep channels tend to provide a thermal refuge during the passage of cold fronts.

4.03 During construction and maintenance dredging, of the channels some turbidity would be created along the bottom in the immediate vicinity of the dredge cutterhead. Huston (1976), studying a cutterhead dredge operating in Corpus Christi Ship Channel (predominantly clay material), found that little of the turbidity created by the cutter went into the upper water column, especially from depths of 30 or 40 feet. Increased turbidity caused by the cutterhead would be considered to be minor and of short duration.

4.04 Noise levels would be elevated in the vicinity of the dredging operations. Air quality would be affected for a short period of time by the consumption of fuel and resulting engine exhausts of the dredging equipment. Neither would be considered significant increases over existing noise and air quality levels for the area.

4.05 A salinity wedge extends from the Gulf of Mexico along the bottom of the existing Mobile Ship Channel and up the Mobile River. The salinity concentrations vary seasonally according to river discharge with high concentrations (approximately 16 ppt) extending as far upstream as river mile 10 during low flow. According to model studies (discussed in section D of the Survey Report and paragraphs 4.42 - 4.47 of this EIS) the enlarged channel would allow more of the high salinity gulf waters to travel northward through the bay and thereby increase the salt wedge intrusion in the river. The upstream boundary of the wedge would remain somewhat unchanged, however, the lower 5 miles of the river would be subject to salinity intrusion for longer periods than presently experienced. The overall hydrological modifications to the bay related to the enlarged channel and disposal plan are discussed in more detail under the cumulative impacts subsection in following paragraphs.
4.06 Impact of Disposal in Bay. Under the Brookley Expansion plan, a total of approximately 1,710 acres of upper Mobile Bay bottoms would be covered with material dredged from the upper bay. Generally, the area is relatively shallow and ranges from four to six feet in depth. This area of the bay has been highly disturbed by man's activities and is characterized by submerged and emergent dredged material deposition mounds, borrow depressions up to 50 feet in depth, remains of the Arlington Pier, and debris that is pulled into the area as a result of the shadowing of river flow by McDuffie Island.

4.07 The area which would be filled constitutes approximately five percent of the bay's bottom that is less than six feet deep. These bottoms are used in sport-shrimping effort and the shoreline furnishes recreational opportunities, including softshell crabbing, castnetting for mullet, and floundering. However, no quantification of the annual use of the area is available. Swingle, Bland, and Tatum in a study on the 16-foot trawl fishery reported that the majority of the sport fishing effort in the early spring and late fall was directed toward upper Mobile Bay and that approximately 14.7 percent of the 5,727 fishermen owning trawls launch in the Dog River-Deer River area. Some of these fishermen undoubtedly travel up the bay to shrimp and utilize this area. The effect of removal of this area from production in the estuarine system is not known. However, Loesch (1965) and Heath (unpublished 1979) found more shrimp in the western side of the bay than the eastern side. They found small brown and white shrimp in greatest abundance in water depths of less than 4 feet and 2 feet, respectively. Heath's sampling, conducted in 1977 and 1978, revealed that the largest "catch per unit effort" for shrimp occurred just north of Dog River and off of East Fowl River.

4.08 Bottom sediments in the proposed disposal area are classified as silty sand, clayey silt, and sand-silt-clay mix. According to Parker (1973), the productivity of the benthos and nekton is closely tied to the kinds of sediments on or in which animals live. Unconsolidated sediments with the highest standing crops are usually poorly-sorted sand-silt-clays or clayey sands of sandy silts, while the poorest sediments for animal life are well-sorted, pure fine sands or clays (Parker, 1969). Parker (1973), however, included the upper third of Mobile Bay in his classification of areas which were least sensitive to increased or additional disturbance. May (1973) in a study on dredging indicated that both standing crop and diversity are lower on the west side of the bay than on the east side and that the ship channel seemed to form an effective barrier between the habitats.

4.09 Parker (1960) described the upper bay bottom which would be filled as supporting river-influenced, low-salinity benthic assemblages. Approximately 20% of the bay is characterized in this manner. The dominant benthic organism in this portion of the bay and down to Dog River is the brackish water clam, Rangia cuneata. Clams smaller than 30 mm are utilized as food by many fishes, crabs, and ducks. Hopkins, et al (1973) has examined Rangia as an overall indicator organism which could be used to determine the effects of engineering works on the biota of coastal waters. The most critical factor in determining the future of Rangia population is in the pulsing of freshets into an embayment, which would not be changed by implementation of this alternative. Although the remaining population outside the fill area would not be directly affected, the fill would destroy a large percentage of the existing populations.

Appendix 1
4.10 The Brookley Expansion area would abut an existing man-made fill area. This area is characterized by about 70 acres of marsh which has voluntarily established along the shoreline. Plant species mainly include Panicum sp., Phragmites communis (common reed), Hydrocotyle umbellata (Pennywort), Iva frutescens (marsh-elder), Myrica cerifera (wax myrtle), Quercus nigra (Water Oak), Zizania aquatica (wild rice), Spartina patens (salt meadow hay), Silax nigra (black willow), Cladium jamaicense (sawgrass), Baccharis halimifolia (groundsel tree), Typha latifolia (common cat-tail), Daubentonia punicea, and Pinus sp. A large part of the wetlands area has been significantly disturbed by trash dumping and fill activities. Construction of the Brookley Expansion area disposal site would eliminate this wetland area. The recommended plan provides for a marsh establishment program which will offset the wetland loss. This and other mitigation features are discussed in detail in section 6.

4.11 Interim guidelines for the disposal of dredged or fill material into navigable waters were promulgated by the Environmental Protection (EPA), pursuant to section 404(b) PL 92-500, and printed in the Federal Register of 5 September 1975. These guidelines have evolved along with research on the impacts of dredged material disposal. As a result, the interim guidelines indicate that the elutriate test, total sediment analyses (bulk analyses), and bioassays may be used to evaluate the chemical-biological interactive effects of the disposal of dredged material. The elutriate test was developed by the Corps of Engineers (COE) and the EPA to determine the potential release of contaminants in the dredged material to the receiving water column. The advantage of the elutriate test is that it simulates the mixing of sediment and water that occurs during the dredging process, however, it does not take into account additional dilution after discharge. To the extent permitted by the state of the art probable effects on sensitive marine organisms can be best be estimated by appropriate bioassays. Bioassays are procedures that use living organisms to detect or measure presence of available toxic, inhibitory, or stimulatory substances. As with the elutriate test static bioassays represent a worst-case situation since the test does not take into account dilution or mixing by water currents and dispersion as would occur at a disposal site.

4.12 A number of detailed studies have been conducted in Mobile Bay over the past decade evaluating the effects of open water disposal of dredged material. Recent studies conducted as a part of the overall COE Dredged Material Research Program have utilized both the elutriate and bioassay techniques of analysis. Results of these studies are summarized in following paragraphs.

4.13 Windom (1973) investigated changes in heavy metals concentrations resulting from maintenance dredging of the Mobile Ship Channel. Metals studied were: iron, cadmium, copper, lead, mercury, and zinc. He concluded that dispersion by dredging is not followed by metal releases of any significant quantity except briefly in the case of zinc and iron. It was further determined that variations in levels of various metals in waters of Mobile Bay showed no relation to dredging activities but appeared to be more influenced by natural processes such as runoff. Slightly increased levels of metals in the water column were found near the
discharge end of the dredge pipeline but these were very localized. May (1973) had similar findings when studying channel dredging in lower Mobile Bay. He concluded that the dredge effluent did not increase the levels of dissolved heavy metals.

4.14 Lee et al. (1978) conducted a water quality study related to the June 1976 Mobile Ship Channel maintenance dredging near Middle Bay Light. Modified elutriate tests performed with the channel sediments and site water prior to dredging indicated that manganese and iron would be released to the water column. Both nickel and copper were removed from the waters while no significant changes occurred for cadmium, chromium, zinc, and lead. Total ammonium and ammonia also displayed a tendency to be released to the water column. Bioassays were performed with the elutriate waters to determine the effects on grass shrimp Palaemonetes pugio. No toxicity was observed during the 96-hour tests. Results of field tests of the actual dredge discharge were comparable to the elutriate tests but indicated only local increases in polluted constituents in the water column directly associated with the initial mud-water matrix discharged from the dredge pipe. As a result of the Mobile Bay study and similar studies of other dredging projects, Lee et al. concluded that the relatively rapid dispersion of any released contaminants at the disposal site creates a situation where the likelihood of significant toxicity or bioaccumulation of contaminants present in the dredged sediments is very small.

4.15 Shuba, Carroll, and Wong (1977) conducted algal bioassays utilizing Dunaliella tertiolecta exposed to various combinations of elutriate and disposal site water concentrations for Arlington Channel. They asserted that an algal bioassay of the elutriate could indicate the bioavailability of constituents released from dredged material and the possible effect on phytoplankton productivity at the disposal site. Elutriate analyses indicated ammonia-nitrogen, TOC and TIC were released from all of the Arlington Channel sediments sampled. Some orthophosphate was removed by all sediments. For the heavy metals, manganese and to a more limited extent lead and nickel were released for all sediments. Results of the bioassay analysis indicated a trend of inhibition to the growth of D. tertiolecta. When nutrients were added to the elutriates growth yield increased significantly. Since ammonia nitrogen was released from all sediments a separate experiment was conducted using D. tertiolecta and concentrations of ammonium up to 49 ppm. The ammonium study demonstrated that the concentrations of ammonium plus ammonia found in the elutriates were not toxic to the test alga. It was suggested that the algal growth in the bioassays could have been affected by the high concentrations of manganese in the elutriates.

4.16 In 1974 the Mobile District Corps of Engineers collected sediment core samples along the alignment of the Mobile and proposed Theodore Ship Channels. Analyses (data contained in sections B and D of Appendix 5) included physical, chemical, heavy metals, bacteriological, and particles by the bulk analyses technique, and elutriate analyses for chemical and heavy metals constituents. Results of the elutriate analyses...
for the sandy upper bay sediments were similar to the elutriate findings of Lee et al. (1978) and Shuba et al. (1977) in that the nutrient related constituents, such as ammonia nitrogen and total kjeldahl nitrogen, displayed the greatest potential to be released to the water column. Analyses of heavy metals in the dike construction material, however, indicated only nickel and zinc would be released to the water column. The EPA Quality Criteria for Water, 1976, indicates that concentrations of nickel below 100 ppb should not be harmful to marine organisms. The concentrations of nickel associated with the dredging operation are well below that value (54.5 ppb). Although there are no specific criteria for zinc the increased concentrations would be relatively small. Based on the results of the previously discussed studies of dredging activities in Mobile Bay, any release of pollutational constituents to the water column would be expected to be transitory and limited to the immediate vicinity of the discharge point.

4.17 Lackey, et al. (1973) studied the effects of maintenance dredging of the Mobile Ship Channel on selected biological parameters. It was concluded from the study that the dredging did not influence the concentrations of coliform bacteria in the water around the discharge, in the sediments of the disposal area, or in the sediments elsewhere. Consequently dredging and disposal of the dredged material for the proposed project would not be expected to modify water quality from a bacteriological standpoint.

4.18 Water quality in the vicinity of the disposal operation will be affected by high chemical and biochemical oxygen demands associated with finely-sorted channel sediments. Resuspension of these sediments results in a temporary reduction in dissolved oxygen. Lee et al. (1978) associated depressed dissolved oxygen levels to the high suspended solid concentrations in the immediate vicinity of the dredge discharge point.

4.19 Increased turbidity and suspended solids concentrations would be associated with the island and expansion area during construction and stabilization. The term turbidity properly refers to optical properties of water having to do with light adsorption and scatter, but turbidity is commonly attributed to suspended sediments alone. It is used in this sense to refer to a broad spectrum of conditions, varying from what can essentially be considered a highly fluid mud, having several grams of particulates per liter, to particle suspensions of a few milligrams per liter, which appear clear to the eye. Varying ranges of turbidity are experienced in most aquatic ecosystems, including Mobile Bay (15-100JTU's), to which resident fauna and flora are adapted (Hirsch, et al. 1978). Background suspended solids values have been documented to range from 4 to 144 mg/l (May, 1973) for Mobile Bay.

4.20 May’s study (1973), for disposal of dredged material in the lower bay, indicated turbidity on the surface did not exceed 35(JTU) above ambient level beyond 400 feet from the end of the discharge pipe. At mid depth this value extended to a maximum distance of 1,200 feet in one direction but was otherwise confined to within 600 feet of the discharge point. High concentrations of suspended solids in the form of a fluid mud layer along the bay bottom extended out to a distance of at least 1,800 feet.
4.21 Nichols and Thompson (1978) conducted a study of turbidity and fluid mud flows associated with Mobile Ship Channel maintenance dredging near Middle Bay Light in June 1976. The discharge was conducted with a 24 inch pipe submerged five feet below the water surface at approximately a 30° angle. Results of the study indicated that the disposal increased suspended solids in near-surface water above background in a zone extending about 1,000 feet along the axis of a plume from the discharge point. Corresponding near-bottom concentrations extended more than 1,950 feet and laterally about 1,300 feet from the discharge point. The discharge plume disappeared within two hours after the dredge discharge was stopped. An estimated 99 percent of the dredged material accumulated as dense suspensions of fluid mud along the bay bottom with concentrations ranging from 10 to 480 g/l. The fluid mud extended more than 1,600 feet from the discharge point at a thickness of about five inches.

4.22 Brett (1975) conducted a sediment dispersion study of the maintenance dredging operation studied by Windom and Lackey. It was reported that the dredged material moved from the discharge as a meandering stream and occasionally resurfaced. These patches of suspended material occurred for a maximum distance of 2,000 to 3,000 feet from the point of discharge. Mud flows were observed to move a distance of about 5,000 feet, while small concentrations of fine materials move up to 4,000 feet from the discharge. Brett also concluded that turbidity produced by dredging settles out within one to two days, and that the dredged material probably stabilizes in at least nine months and then becomes difficult to resuspend because of the high concentration of clay particles contained in the dredged material.

4.23 The disposal operations would increase suspended solids throughout the area during the period of construction and stabilization of the dikes, which may involve a period of several years. Heavy suspended solid concentrations would be expected in the area of construction, but small quantities of colloidal-sized particles of dredged material would be transported by currents and tides and could be expected to visibly increase turbidity over a wide spread area of the bay. The area that would be influenced by excessive turbidity would include the disposal site and those areas which would be temporarily disrupted by mud flows. Under worst-case conditions, utilizing the findings of Brett (1975), during construction of the upper bay expansion area approximately 1,300 acres of water bottoms west of the ship channel off Brookley would be subject to impact by mud flow in addition to the 1,710 acres of bay bottom committed to the disposal area.

4.24 Conceptualized impacts of excessive turbidity and suspended material which may be encountered in the bay include interference with filter-feeding activities of invertebrates, irritation and clogging of the gills of fish, and interference with plant photosynthesis due to shading effects. The responses of aquatic organisms to turbidity are frequently difficult to determine because they may be due to a wide variety of causes, including, but not limited to, the following: concentration of suspended solids, the number of particles in suspension, their densities, size distribution, shape, minerology, sorptive properties or presence of organic matter and its form; inherent physical, chemical, and biological characteristics of each site; and antagonistic and synergistic effects. Other variables, such as the interaction between the solids, temperature, and dissolved oxygen, frequently affect aquatic organisms before and during the increase in turbidity. For a more precise understanding of the impacts due to turbidity suspended solids and mud flows on the natural resources
of Mobile Bay, the following parameters are discussed in more detail:
Habitat, primary productivity, benthic assemblages (benthos), invertebrates, plankton, nekton, fishes, and aesthetics.

4.25 As discussed in paragraph 4.21 the area around the disposal site would be blanketed with a thin layer of material which would obviously result in habitat alteration. According to St. Amant (1972) investigations in Louisiana into the effects of dredging activities on normal benthic populations indicate that the findings in these areas differ to some extent and in many cases are highly variable. In general it is recognized that during the initial disposal operation those benthic organisms in the immediate vicinity of the discharge are severely disturbed and either scattered or destroyed. However, the disposal areas tend to restore themselves in a short period of time. This is expected since most of the animals are naturally short-lived and have a high reproductive capacity. This type of biological resilience furnishes the mechanisms required for survival of populations of such lower animal forms. St. Amant (1972) indicates that the disposal areas would be expected to be repopulated within a normal growth season.

4.26 Studies by Oliver, et. al. (1977) indicate that organisms, especially polychaetes, initially recolonizing dredged material were not the same as those which had originally occupied the site and consisted of opportunistic species whose environmental requirements were flexible enough to allow them to occupy the disturbed areas. According to studies by Hirsch et. al. (1978) trends toward reestablishment of the original communities were noted within several months after disturbance and complete recovery was approached within one year. Vittor (1974) noted that in D'Olive Bay, Alabama, benthic invertebrate standing crop was decreased by dredging and the mud flow was responsible for significant prolonged loss of infauna biomass. Although an overall 28 per cent decrease in benthic invertebrate biomass occurred, benthic species diversity was not significantly lowered.

4.27 Laboratory tests at the Corps of Engineers Waterways Experiment Station, Vicksburg, Mississippi indicate that most motile inhabitants of the substrate are able to move vertically through dredged material. However, the physical characteristics of the sediment overburden are very important in the process of vertical migration. The laboratory tests show that when dredged material is physically similar to that in which the animals normally occur, there is little problem in accomplishing vertical migration. During the tests the majority of animals were able to migrate vertically through approximately 12.5 inches of dredged material. Although these studies duplicate to some extent the conditions which might occur during a typical disposal operation, there are obviously some parameters which are not duplicated. However, generally it would appear that animals, especially polychaetes, do migrate through dredged material since they are found in the disposal material shortly after the operation ceases.

4.28 A decrease in the depth of the lighted or euphotic zone usually accompanies increased turbidity (Sherk, 1971). As a result, the most
frequently cited negative aspect of dredged material disposal is the reduced photosynthetic activity due to the interference of light penetration. However, the addition of suspended material can also stimulate photosynthesis by increasing the available nutrients (Stern and Stickle, 1978). Turbidity and suspended materials produced as a result of natural and/or man's activities can therefore either promote or inhibit primary production, and can be of substantial importance. Because so little information is available on the relationship between dredging activities and primary productivity, it is difficult to relate the time duration of turbidity caused by dredging, and the dilution around the disposal site, to the time required for algal stimulation or inhibition. According to Flenner (1970) short term dredging, as in maintenance operations, usually produces only temporary effects, and upon cessation of dredging primary productivity returns to normal levels. Because of the amount of fines associated with the dredged material it is expected that phytoplankton productivity would essentially be eliminated in the immediate area of dike construction during the discharge operation and for a short time thereafter until the dikes become stabilized.

4.29 Suspended sediments may also affect the abundance of planktonic forms and be of direct harm to zooplankton, fishes, and motile invertebrates. Several studies suggest that suspended particles raised by dredging have no gross effects on the diversity or abundance of zooplankton nor the composition of fish eggs and larvae (Dovel, 1970; Goodwyn, 1970). However, other investigations indicate that periodic resuspension of silts and clays by repeated dredging or wind and wave action may adversely affect the general metabolism of adult plankters and both metabolism and metamorphosis of fish eggs and larvae as well as other developmental stages (Sherk, 1971, and 1972; Livingston, et.al., 1972). Simon and Dyer (1972) indicate that clumping and flocculation of plankton with suspended particles and subsequent settling to the bottom decreases planktonic populations. Lackey, et.al. (1973) and Markey, et.al. (1975) report a transitory decrease in the immediate vicinity of the dredge discharge during maintenance dredging.

4.30 Turbidity and suspended material may affect fishes directly or indirectly. Direct effects according to Stern and Stickle (1978) could include lethal agents and those factors that influence physiological activities (reproduction, growth, development) or produce abrasive wear on tissue. Indirect effects include modifications to habitats and food chain organisms. Recent data, based upon weight/volume concentrations of suspended solids, from several closely monitored laboratory studies are probably more indicative of natural responses of adult fishes to suspended solids (Stern and Stickle, 1978). The results of these studies have indicated that adult fishes, as well as invertebrates, are affected by a complex interaction between suspended solids, temperature, and dissolved oxygen. A correlation exists between normal habitat and sensitivity to suspended solids with the most tolerant species being the bottom dwellers while the filter feeders are the most sensitive. High suspended solids would be less harmful in winter than in summer and fishes as a group are more sensitive to suspended solids than many of the invertebrates studied to date.
4.31 Based on Stern and Stickle (1978) and studies conducted in D'Olive Bay Alabama by Vittor (1974) most fishes usually migrate out of the dredging area and gross effects to fishes are rarely observed. Patterns of seasonal occurrence, abundance, species diversity, and conditions of the gill filaments among fishes exposed to dredging operations and dredged material disposal generally remain unchanged. Under normal circumstances fish avoid turbid waters and have the ability to clear membranes of accumulated silt upon entering undisturbed water. Most studies have indicated that upon exposure to temporary increases in turbidity and suspended material similar to that encountered in areas where dredging or the disposal of dredged material has occurred no permanent effects were exhibited.

4.32 The turbidity associated with the open water dike construction and stabilization would be aesthetically displeasing to some people. Most complaints from the general public concerning maintenance dredging and shell dredging involve localized turbidity and/or disturbances which for a period of time may reduce localized fishing success in the vicinity of the operations. David (1971) found that although water pollution is perceived by the general public to be of increasing concern and that the public has rather definite ideas about what constitutes a description of pollution, very often aesthetic criteria are used. She discovered that the most widely used indicators of water pollution seem insufficient in light of the public definition of and concern about water pollution. Therefore the degradation to aesthetics associated with the project is of importance and would be minimized to the extent practicable.

4.33 In response to concern over the potential impact of suspended solids and turbidity associated with dredged material disposal one task within the Corps of Engineers Dredged Material Research Program, conducted at the Waterways Experiment Station, was to evaluate methods for controlling the dispersion of dredged material. Results of the studies indicate that the most promising method for controlling water column turbidity and mud flows involves modifying the pipeline configuration at the discharge point. It was found that the amount of water column turbidity generated by a submerged discharge decreases as the angle of the pipeline discharge increases from 0 to 90 degrees. By adding a 15 degree conical section at the end of the 90 degree elbow, the effective velocity of the discharged slurry can be reduced by a factor of 2 or 3 (without affecting the dredge's production rate). This decreases the levels of water-column turbidity and increases the mounding tendency of the fluid mud. Laboratory tests involving the control of dredged material dispersion have resulted in the development of a submerged diffuser system (figure 3). Although the diffuser has not been field tested, it has a great deal of potential for most effectively eliminating turbidity in the water column and maximizing the mounding tendency of the discharged dredged material, thereby minimizing the aerial coverage of the fluid mud flow. The slurry remains in the pipeline/diffuser until it is discharged at a low velocity near the bottom, thus preventing any interaction of the slurry with the water column above the diffuser. This eliminates water column turbidity as well as any depression of the dissolved oxygen levels in the water column. A system for control of dredged
Figure 3
SUBMERGED DIFFUSER DISPOSAL SYSTEM
material dispersion would be environmentally beneficial for the open water dike construction in the upper bay, and will be considered further post-authorization studies.

4.34 Results of engineering and environmental monitoring studies to be conducted in conjunction with construction of the disposal island for the Theodore Ship Channel project, as discussed in Section 1, will be utilized in development of the disposal plan for the upper harbor area. Also, results of the Mississippi Sound study currently being conducted will be beneficial to the Mobile Harbor project. These studies will be coupled with a bay usage study to be developed and conducted during post-authorization studies. The purpose of the usage study will be to define biological productivity, gather water quality data, and predict recreational potential for various sections of the bay. This will provide a better comparative analysis of the environmental impacts of the bay disposal operations.

4.35 After completion of the open water dike construction the remaining new work material from the upper bay would be placed within the confines of the expansion area. The impacts of disposal would be minimal with sufficient ponding and proper placement of the weirs to provide drainage from the disposal areas toward the open portion of the bay.

4.36 Impact of Offshore Disposal. Under the proposed plan approximately 58,654,000 cubic yards of new work material from the lower bay channel, south of Theodore, and an average annual volume of 4.1 million cubic yards of maintenance material from the entire bay channel would be excavated by hydraulic dredge utilizing dump scows and tow boats to transport the material to a gulf disposal area. During construction of the bar channel approximately 19,019,000 cubic yards of material would be removed by hopper dredge and dumped in a gulf disposal area(s). On an average annual basis about 379,000 cubic yards of maintenance material would be dredged from the modified bar channel and placed offshore.

4.37 The location of offshore dredged material disposal sites would have to be designated by the EPA in accordance with the 11 January 1977 Ocean Dumping Criteria, developed pursuant to the Marine Protection, Research, and Sanctuaries Act of 1972, PL 92-534. In selection of the disposal site the criteria requires that in addition to other necessary or appropriate factors determined by the EPA, the following factors would be considered:

(1) Geographical position, depth of water, bottom topography and distance from coast;

(2) Location in relation to breeding, spawning, nursery, feeding or passage areas of living resources in adult or juvenile phases;

(3) Location in relation to beaches and other amenity areas;
(4) Types and quantities of wastes proposed to be disposed of, and proposed methods of release;

(5) Feasibility of surveillance and monitoring;

(6) Dispersal, horizontal transport and vertical mixing characteristics of the area, including prevailing current direction and velocity, if any;

(7) Existence and effects of current and previous discharges and dumping in the area (including cumulative effects);

(8) Interference with shipping, fishing, recreation, mineral extraction, desalination, fish and shellfish culture, areas of special scientific importance and other legitimate uses of the ocean;

(9) The existing water quality and ecology of the site as determined by available data or by trend assessment or baseline surveys;

(10) Potentiality for the development or recruitment of nuisance species in the disposal site;

(11) Existence at or in close proximity to the site of any significant natural or cultural features of historical importance.

The results of a disposal site evaluation and designation study based on the above criteria would be presented in an environmental impact statement prepared by the EPA.

4.38 One area being considered for a new gulf disposal site is located about 16 miles southwest of the mouth of Mobile Bay in water exceeding 70 feet deep (figure 4). The disposal area would cover approximately 24,600 acres. According to Vittor (1977) the area is characterized by a coarse to medium sand bottom with occasional clusters of shell hash. Two varieties of bivalve, Ammonia beccarii, abundant in the area, are tolerant to a high degree of stress. Their presence in abundance appears to reflect the influence of heavy sedimentation of fine material from the Mississippi and Mobile Rivers. However, it is doubtful that these forms could tolerate the large quantities of material resulting from the proposed project. Personnel of the Dauphin Island Sea Laboratory have indicated that the general area is characterized by a nepheloid layer at various times of the year, but that an abundant and diverse standing crop is quickly established whenever it is absent. This suggests a high degree of ecosystem resilience. Prevailing currents within 30 miles of Dauphin Island travel from east to west. Consequently, a gradual shifting of the lighter sediments to the west is expected.

DREDGE DISPOSAL
Appendix I
4.39 A preliminary report, completed under contract by TerEco Corporation, as a part of the Mississippi Sound Study, indicates suitable offshore sites based upon the summation of published and pertinent unpublished information relative to environmental and biological characteristics of the nearshore seabed within the study area. As shown on figure 5 the report focuses upon those specific areas where dredged material disposal is likely to cause the least damage to features and processes of greatest environmental and social value.

4.40 The 11 January 1977 Ocean Dumping Criteria established by the EPA require that elutriate tests and biological evaluations be performed prior to disposal of dredged material offshore. Elutriate results (Section D Appendix 5) for gulf disposal of the lower bay material were similar to that previously discussed for other bay sediments. The nutrient related constituents displayed a potential to be released to the water column along with a minor increase in some of the heavy metals concentrations. Sediments collected from the main bay channel near the intersection of the proposed Theodore Channel exhibited the greatest potential for undesirable effects on the water column. "Three phase" (liquid, suspended particulate, and solid phase) bioassay analyses required by the EPA were performed with these sediments to simulate a worst-case situation. Bioassay results, contained in Section D of Appendix 5, indicate that there would not be any significant lethal effects from the dredged material on zooplankton, crustaceans, fish, infaunal bivalves, or infaunal polychaetes. Also, Mercenaria mercenaria (Infaunal bivalve) exposed to the solid phase of the dredged material did not demonstrate a potential for bio-accumulation of heavy metals, pesticides, or petroleum hydrocarbons.

4.41 As noted by letter of 2 November 1979, Appendix 3, the Environmental Protection Agency has issued a statement of concurrence on the availability of Gulf disposal sites within a reasonable distance to Mobile Bay, as described in above paragraphs. Detailed site specific evaluations will be conducted next as a part of post-authorization studies. The Mobile District Corps of Engineers is maintaining coordination with the EPA relative to the site designation requirements and procedures are being established for further disposal site evaluations. In addition, the EPA is currently preparing a "regional generic" EIS for the offshore area from Gulfport to Pensacola in order to establish site designation for maintenance material presently being placed in interim-approved areas.

4.42 Cumulative Impacts of the Proposed Plan. In order to determine the hydrological impacts of the proposed project, physical model studies of the bay were conducted at the Corps of Engineers Waterways Experiment Station, Vicksburg, Mississippi. Elements studied included tides, velocities, surface currents, and salinities. Figure 6 shows the location of the test stations used in the model. Initial tests, discussed in Section 6, were conducted for a number of disposal plans with a low freshwater inflow of 15,500 cubic feet per second (cfs). After initial studies were completed more detailed tests

were conducted for a favorable disposal plan, figure 7, with a mean freshwater inflow of 63,500 cfs and a tide range of 2.3 feet at the Dauphin Island gage. Due to the substantial lead time required to complete the tests in phase with other studies for Mobile Harbor the model studies were conducted prior to optimization of channel dimensions and refinement of disposal plans. As such, the tests were conducted with a 50-foot deep and a 500-foot wide channel as suggested by local interests and the upper bay disposal plans accounted for maintenance material from the upper harbor channel. Final results of the survey studies indicated that the optimum channel dimensions would be 55 feet deep by 550 feet wide, and it would be more economical and environmentally acceptable to transport the upper harbor maintenance material to the gulf rather than construct the Little Sand Island disposal area for that purpose. Further details of the study process are discussed in Section D of Appendix 5.

4.43 Although none of the model tests represented the exact features of the proposed plan, the features tested provided an increment of change adequate to identify patterns of change in the bay that could result from the proposed modifications. Therefore conclusions from the detailed model tests are as follows:

a. There were only minimal changes in the tidal heights in the bay for this plan. Cedar Point showed the only significant differences with a low-water elevation of 0.4 feet higher than the base condition.

b. Surface maximum ebb velocities were slightly (0.4 to 0.5 fps) decreased at sta 2, 3, and 9 slightly increased at sta 5 and 10. Sta 8 surface maximum ebb velocity increased from 3.0 to 3.7 fps due to the Brockley fill and the nearby disposal island. Surface maximum flood velocities were reduced from 2.3 to 1.7 fps at sta 2 and increased from 0.8 to 1.5 fps at sta 3. Bottom maximum ebb velocities were not greatly affected. Sta 6 and 8 showed slight decreases and sta 10 had a slight increase. Bottom maximum flood velocities were slightly reduced in the lower reach of the channel (sta 1, 2, and 3) and also in the upper reach at sta 9. Slight increases occurred at sta 6 and 7.

c. The percentage of total surface flow downstream was not significantly changed by this plan. However, the lower end of the channel was less ebb predominant (significant reduction at sta 3). The percentage of total bottom flow downstream was decreased throughout most of the channel length (bottom flow had an increased flood predominance).

d. The surface current observations indicated that the disposal areas of the tested plan relative to the Gulf Disposal plan: increased ebb velocities in the channel and also increased flow through the pass between Pinto Island and Little
Sand Island. During strength of ebb, the diagonally cross channel velocities south of the disposal island are increased relative to the Gulf Disposal plan.

e. The average surface and bottom salinity over a tidal cycle in the bay increased for stations in the upper bay and near the channel. Average salinity in the lower bay was significantly reduced east of the navigation channel, while station salinities west of the channel usually increased. There seems to be an increased supply of saltwater from the enlarged channel and a greater storage of freshwater in the Bon Secour Bay area.

f. Changes in maximum or minimum salinities in some regions were quite different from those of the average salinity. In many cases, the maximum salinity was more severely changed than was the average.

g. The salinity intrusion length up the Mobile River was increased at the bottom depths for this mean freshwater inflow.

h. The average surface salinity was increased in all for critical oyster bed areas. The maximum increase was 2.1 ppt. Bottom average salinities were increased at the areas south of the Theodore Channel (+1.6°/oo) and reduced at Whitehouse (-1.1°/oo) and Klondike (-2.2°/oo) critical areas. Status quo was maintained at Cedar Point critical area.

4.44 The proposed plan resulted in moderate changes in surface and bottom salinities in the upper bay. The greatest increases occurred near the channel for both surface (+2.5 °/oo) and bottom salinities (+3.4 °/oo). Although a moderate freshening of the bottom waters of the nearshore stations was evident, the general trend was to increase the upper bay salinities. This finding, in conjunction with the widespread freshening of Bon Secour Bay (5.9 °/oo highest average top and bottom change at the station having the greatest change), strongly suggests that Mobile Bay's existing hydrographic characteristics would be significantly modified. The maximum freshening in Bon Secour observed at any one locality in the bay was at station M-5 (about four miles SSW of Mullet Point) and was 11.7 °/oo on the bottom over a single hour in the tidal cycle. Additionally, bottom salinities at this station were decreased at least 6 °/oo during 96% of the tidal cycle.

4.45 These changes are the apparent result of the deepened channel which increases the salt wedge intrusion up the Mobile River. The dense salt wedge apparently plugs much of the channel and restricts the southward flow of the less dense freshwater which is consequently diverted within the distributary system toward the eastern branch, the Tensaw, somewhere in the upper delta. This water sweeps the eastern shore and results in the overall freshening of Bon Secour Bay. An additional factor which intensifies
the freshening effect apparently relates to the relationship of the channel size and the salt wedge in the lower bay. It is possible that the hydraulics of the enlarged channel prevent the salt wedge from creeping up and eastward into Bon Secour Bay, consequently reducing its supply of highly saline gulf water. This tends to increase the freshening effect since the lost saline waters would be replaced by riverine and partially mixed bay waters having less salt content. Although additional investigation is required, it is possible that this change would resemble the manner in which the lower bay operated prior to ship channel construction.

4.46. The impacts resulting from this change are widespread and effect almost every environmental feature within the bay. Some of the changes are obviously beneficial, others are negative or harmful. The direction of most of the changes is unknown. Although the impacts cannot be analyzed in detail at this level of investigation, they include:

1. A decrease in the waste assimilative capacity within the Mobile River.
2. Increased turbidities along the eastern shore.
3. Long-term alteration of marsh types within the Bon Secour Bay.
4. Increased oyster producing area within Bon Secour Bay with the possibility of improved spatfall.
5. Increased frequency of closure to shellfish harvesting of Bon Secour Bay.
6. Unquantified changes in the overall nursery value of Mobile Bay.
7. Alteration of the flushing characteristic of Mobile Bay as determined by dye diffusion studies.
8. Alteration of larval migratory pathways.

4.47. The basic goal of the model studies is to develop a plan that will maintain as near as possible the existing general pattern of circulation and the salinity regimen throughout the bay. Therefore additional model tests would have to be conducted for the proposed plan during post-authorization studies to determine the effects of the 55-foot deep channel and required mechanisms for offsetting significant hydraulic effects of the enlarged channel.
4.48 Two dredges could be operating continuously during construction of the proposed project. In conjunction with this a possibility exists that a number of dredges could be simultaneously operating in various portions of Mobile Bay for an extended period. Presently, maintenance dredging of the existing Mobile Harbor project requires about eight dredge-months per year. Normally the work is accomplished with one dredge but occasionally two are employed. Inclusion of maintenance dredging from the proposed Theodore project would approach twelve dredge-months per year, which would be accomplished with two or three dredges. The dredging of dead reef oyster shell is conducted in the bay on a year-round basis. Smaller dredges operating infrequently and for much shorter periods of time are employed in maintaining Fowl River, Dauphin Island Bay, Fly Creek, Bon Secour River, and the Gulf Intracoastal Waterway.

4.49 Implementation of the proposed plan would, in effect, involve open-water disposal of dredged material in the upper bay during the construction period. Adverse impacts associated with the various dredging projects within the bay relate to open-water disposal. The major adverse impacts include turbidity, siltation and mud flows, and loss of benthic invertebrates. These effects are generally localized and are confined to the duration of the dredging operation. Since maintenance dredging of the proposed project would not involve open-water disposal in the bay, the dredging-related cumulative impacts of the project with other activities would only occur during the construction period. As discussed in paragraphs 4.08 and 4.23 the maximum area of the bay which would be subject to excessive suspended solids movement during construction would be 2.7 square miles committed to the disposal area and 2.0 square miles attributed to mud flows. The construction period estimated at seven years, would progress simultaneously with operation of the shell dredge and the channel dredges in maintenance of the Mobile Ship Channel and the Gulf Intracoastal Waterway. Other mentioned projects are either very small, sufficiently removed, or involve confined disposal and are not considered significant relative to the entire bay. The total maximum area of the bay which would be subject to excessive solids movement instantaneously as a result of the shell dredge and channel maintenance dredges is about 3.5 square miles. Thus implementation of the plan would increase the total maximum area of the bay subject to excessive suspended solids movement from about 3.5 square miles to nearly 8.2 square miles for the period of construction and stabilization of the dikes in the upper bay. Although a maximum of 8.2 square miles may be affected if operation of all the dredges did, in fact, overlap, the long term cumulative effects on the bay would be less than under the existing maintenance disposal.
practices since after construction of the project is complete the only open water disposal in the bay would be from the shell dredge, intracoastal waterway and some of the other mentioned small projects.

4.50 Based on the discussions in section B of the Appendix 5, construction of the proposed project could affect some sites of historical interest. A complete cultural resources survey would be required prior to new channel construction and the use of new disposal areas. A remote sensing survey would have to be conducted at all water construction and disposal areas, including the offshore site. Delineated anomalies located within construction or disposal areas, if not avoided, might require an evaluation of significance for the National Register of Historic Places in accordance with the National Historic Preservation Act of 1966, PL 89-665.

4.51 Impact of Project on Threatened Fish and Wildlife. Implementation of the proposed project is not expected to have significant detrimental effects on threatened fish and wildlife which may appear in the area. All of the construction activities within the bay will be in areas that have been subject to disturbance by periodic maintenance dredging, dredging for fill, or port related activities. Proper contact has been made with the US Fish and Wildlife Service implementing coordination procedures in accordance with the Endangered Species Act of 1973. By letter of 14 October 1980, Appendix 3, the Fish and Wildlife Service, Jackson, Mississippi, indicates that "although several Federally-listed species may occur within the project area, they would not be affected by the proposed activity."

4.52 Secondary Impacts of the Proposed Project. As discussed in Section D of the Survey Report, certain socio-economic trends expected to occur in the area under the "no action" plan would be incited by an unquantifiable amount with construction of the proposed project. There would be an increase in population, employment, housing, industrial and commercial development, water borne commerce, and port expansion. As the population in the study area continues to grow more land now used for other purposes will be converted to urban and built-up uses. This is particularly true for the heavy growth areas west of Mobile and south to Theodore. Baldwin County is also becoming more attractive to residential growth. Concomitant commercial development is expected to occur in the areas of residential development. The location of the industrial spine in Mobile is not expected to change significantly, although the demand for industrial land will increase. Industrial growth is projected to expand primarily along upper Mobile Bay, north along the Mobile River, and south in the Theodore Industrial Park. Expansion of port terminal and handling facilities is also expected to occur with the proposed upper bay disposal site being a primary area of expansion.
4.53 Increased dock activity is not expected to affect the displacement of residential dwellings. There is little residential development in the immediate area of expansion. Most of these existing houses are in delapitated conditions and are subject to urban renewal programs.

4.54 Aesthetic values in the project area are expected to undergo changes as the region responds to the need for industrially developed land and expanded harbor facilities. This expansion can be expected to reduce the amount of open space lands, and render the area less desirable for recreational activities.

4.55 Selection of the proposed plan would not be expected to significantly affect community cohesion in the Mobile SMSA. Certain groups within the region would regard the harbor improvements as a major boost to the economic well-being of the study area while others would be skeptical of alterations to the bay.

4.56 Anticipated growth will create conflicting demands for the study areas' fresh water resources. Much new industry is locating in the region to take advantage of the resource. Continued population growth will also require large amounts of fresh water.

4.57 Water pollution associated with the increased development of the area will be a major concern. As indicated in Section B of Appendix 5, a water quality management plan for Mobile and Baldwin Counties has been developed by the South Alabama Regional Planning Commission in compliance with Section 208 of PL 92-500. In order to effectively improve water quality and assure attainment of water quality goals, the 208 study indicates that a regional structure is needed to coordinate the various city and agency water quality plans and standards. Such a structure would also facilitate the study of point and non-point sources of pollution and other water quality problems from a basin-wide perspective on a continuing basis. If the recommendations of the 208 study are adopted locally, certified by the Governor and approved by the Environmental Protection Agency, then the South Alabama Regional Planning Commission, in conjunction with the Alabama Water Improvement Commission, will be assigned the responsibility to carry out the area-wide management program.

4.58 Since the study area is predicted to experience a continued growth level, the Division of Air Pollution control, Bureau of Environmental Health, which monitors Mobile County's air quality, is presently developing an Air Quality Maintenance Plan for the County. The plan, which is mainly concerned with particulates, will cover the twenty-year period from 1975 through 1995, and will indicate the ambient air levels resulting from increased growth. It will then determine what, if any, additional regulatory measures will be necessary. New industrial development in the county will be subject to stringent regulations and extensive studies will be required to insure that the standards will not be violated as result of the new development. Since most of the study area's industrial growth is expected to occur in Mobile County, Baldwin County is not projected to experience serious degradation to its air quality. It's also expected that when final compliance with Federal automobile emission standards is achieved, there will be a substantial reduction in the photochemical oxidant level. Stringent controls of new industrial development will also be necessary to assure this.
4.59 Noise in the Mobile Harbor area will result primarily from truck and automobile traffic and the operation of heavy machinery associated with loading and unloading at the docks. Since harbor activity is expected to increase it is assumed that noise levels will also rise but not reach the tolerance levels discussed in section B of Appendix 5.

5.01 ADVERSE ENVIRONMENTAL EFFECTS WHICH CANNOT BE AVOIDED.
Unavoidable adverse impacts associated with the project would arise from the dredging and disposal operations which would destroy some benthic populations, increase turbidity, and cause physical loss of some bay bottom habitat and recreational/fisheries areas. There are also other adverse impacts that can be avoided only if remedial measures can be established. These are associated with modifications to overall circulation patterns in the bay caused by channel construction, and sites of historical interest, if any, located within the channel alinement and disposal areas. Secondary impacts would result from economic development of the area enhanced by the project construction.

5.02 Benthic populations would be destroyed by project operations due to channel construction and layers of sediment deposited on the bottom by mud flows during disposal. The amount of bay bottom that would be affected during construction would be about 5.8 square miles including; (a)1.1 square miles due to widening the bay channel, (b)2.7 square miles for the expansion area and (c)2.0 square miles attributed to mud flows during construction of the disposal area. The 2.7 square miles committed to the disposal area would result in permanent loss of esturaine habitat and recreational/fisheries use of that portion of the upper bay. In addition the offshore area affected by the dredging and disposal operations would include 0.8 square miles for modifications to the bar channel and an unquantified area committed to the gulf disposal sites. This will be addressed further in an EIS to be prepared by the EPA.

5.03 A minor release, to the water column, of nutrient related constituents and some heavy metals would occur during the open water disposal operations. The release of polluional constituents would be expected to be transitory and limited to the immediate vicinity of the discharge point. Reduced dissolved oxygen levels would be associated with the initial high levels of turbidity and suspended solids near the discharge point. Increased turbidity would temporarily reduce photosynthesis and, hence phytoplankton, the base of many food chains, would be reduced during the construction period. However, turbidity and mud flows can be minimized by modifying the pipeline configuration at the discharge point. There will also be short-term effects from air pollution and increased noise levels during the dredging operations.

5.04 According to model studies modifications to the bay ship channel would cause a change in the overall salinity distribution within Mobile Bay. This is the apparent result of the deepened channel which increases the salt wedge intrusion up the Mobile River. Additional model tests would have to be conducted for the proposed plan during post-authorization studies to determine the effects of the 55-foot deep channel and if needed, mechanisms for offsetting significant effects of the enlarged channel.
5.05 A complete cultural resources survey of the bottom areas to be affected would have to be completed prior to project construction. Magnetometer surveys of the areas may reveal numerous anomalies. Measures would have to be taken to protect and preserve objects or sites of historical significance, if any, within the channel alignment and disposal areas.

5.06 Secondary impacts of the project would include higher levels of noise, water, and air pollution related to increased economic development of the area. There would be an increase in population, employment, housing, industrial and commercial development, water borne commerce, and port expansion. However, the basic patterns and general magnitude of growth are expected to occur with or without the project.
6.01 ALTERNATIVE TO THE PROPOSED ACTION. As discussed in Section D of Appendix 5, various alternative plans were formulated based upon study objectives to fulfill the needs of the Mobile Bay area. Specific features considered in plan formulation included not only navigation improvements but also the possibility of investigating measures other than identified navigation problems.

6.02 Since any structural alternative would involve excavation of large quantities of material from Mobile Bay, early plan formulation studies concentrated on determining the economic and environmental impacts associated with various dredging and dredged material disposal techniques. It was determined that a hydraulic pipeline dredge would be the most desirable technique for excavation with disposal options of upland, open bay, construction of diked or bulkheaded island and fill areas, or utilization of a fleet of dump scows for Gulf disposal. A hopper dredge could be used for the entrance channel due to the closeness of deep water disposal areas. Other dredging and disposal techniques were eliminated because they were too costly, involved untried and inflexible methods, or utilized foreign equipment to perform the dredging which would not be allowed under current United States Government policy.

6.03 Early studies addressed not only modifications to the existing bay channels but also possibly deepening and widening the proposed Theodore channel. As a result of the initial screening an array of dredged material disposal options was developed which include:

   a. Mobile Bay Island or Fill Alternatives - Five variations of this concept involving dredged material disposal islands and fill areas in both upper and lower Mobile Bay were evaluated. The island and fill areas were considered to contain all new work and maintenance material for a 50 year period. Figures 8, 9, 10, 11, and 12 are illustrative of the five similar plans.

   b. Open Water Disposal Alternative -

       (1) Removal of all new work and maintenance material to the Gulf of Mexico (Figure 13).

       (2) Disposal of all new work and dredged maintenance material along the channels in Mobile Bay in accordance with current practice (Figure 14).

       (3) Removal of all new work material to the Gulf of Mexico and deposition of all maintenance material in open water adjacent to the channel in accordance with current practice.

   c. Upland Disposal - This alternative involves removal of all new work and dredged maintenance material for a period of 50 years to upland disposal sites as show on Figure 15.
Figure 9
MOBILE HARBOR, ALABAMA

Appendix 1
41
d. Combinations of the above -

(1) Mobile Bay Island or fill and Gulf Disposal - This alternative includes disposal areas or islands in upper Mobile Bay for disposal of new work and maintenance material from the upper channel and disposal of new work material from the lower bay and Theodore channels in the Gulf of Mexico. An additional option would be for disposal of a limited amount of new work material along the western shore of the bay to abate erosion problems. Maintenance material from the lower bay and Theodore channels would be disposed by one of two options.

(a) Disposal in Mobile Bay in accordance with current practice.

(b) Transport to the Gulf of Mexico for disposal.

A general depiction of these alternatives is shown on Figure 16.

(2) Theodore Rehandling Plan - This alternative is the same as the preceding plan, with the exception that the new work and maintenance material from the lower Theodore channels would be transported to the proposed Theodore Disposal Island for consolidation and drying and then transported to the Gulf for disposal.

The socioeconomic and environmental effects associated with these dredged material disposal alternatives are summarized in Table 1. Further details of plan formulation are discussed in Section D of Appendix 5.

6.04 Seven dredged material disposal plans formulated during the early studies were evaluated with the physical model of Mobile Bay located at the Waterways Experiment Station, Vicksburg, Mississippi with 50 by 500 foot channels. Five are the Mobile Bay Island and Fill plans which are shown on Figures 8 through 12. Another plan consisted of the 50-foot deep channels with only the proposed Theodore Disposal Island in place representing either the Gulf Disposal Plan or the Upland Disposal Plan (Figures 13 and 15). The remaining plan tested, shown on Figure 16, represents a combination of Mobile Bay Island and Fill and Gulf Disposal Plans with the option for disposal of material along the shoreline.

6.05 The primary environmental objective of the tests was to analyze the effect the larger channel and disposal alternatives would have upon circulation and salinity values within Mobile Bay. The tests were conducted with a low freshwater inflow of 15,500 cubic feet per second (cfs). The base condition selected for evaluation of the seven plans included the existing project conditions for Mobile Bay with the 40-foot Mobile Ship Channel in place and also included the authorized 40-foot Theodore Ship Channel and disposal island.

6.06 Results of the model tests indicated that all plans caused similar salinity changes regardless of island and fill placement. Generally, the changes under low flow conditions included an increase in salinity in the upper bay and a freshening of the lower bay areas. This finding indicates the changes are related more to the enlarged channel than island construction. None of the plans tested maintained the status quo throughout the bay. However, changes in some localities were considered more significant in regard to oyster production. The four oyster producing areas in Mobile Bay that were studied included Cedar Point, Whitehouse, Klondike, and South of Theodore Channel. These four areas and model boundaries are shown on Figure 17. Insofar as overall oyster well-being is concerned, the following ranking of importance, in terms of salinity change was used: Cedar Point > Whitehouse > Klondike = South of Channel. Table 2 displays salinity data from these critical areas obtained during the testing of each plan. Based upon the salinity results, no single plan proved to be significantly better than the others. The plans that showed the least salinity changes were the Mobile Bay Island and Fill Plans shown on Figures 8 and 10. These were closely followed by the Mobile Bay Island and Fill and Gulf disposal Plan (Figure 16) and the seventh plan tested which represents the Upland Disposal Plan or the Gulf Disposal Plan (Figures 13 and 15).

6.07 The selection of plans for detailed consideration was based upon costs, environmental and socio-economic analyses performed, and input from the public including a meeting of the Mobile Harbor Advisory Committee on 5 August 1976, a plan formulation public meeting held in Mobile, Alabama on 22 November 1976, and various working level meetings of environmental agencies and individuals. Along with the "No Action Plan" structural alternatives taken forward for final comparison included four separate and distinct methods of dredged material disposal. These alternatives are as follows:

1. The Brookley Expansion Area and Gulf Disposal Plan No. 1 (proposed plan, Figure 1) which encompasses the features described in Section 1 of this document.

2. Gulf Disposal Plan. This plan would encompass the same channel construction features as the preceding plan, however, it would not include construction of the Brookley Expansion area. All new work and annual maintenance material would be transported to the Gulf of Mexico for disposal.

3. The Brookley Expansion Area and Gulf Disposal Plan No. 2 (NED plan) which involves all the same elements as the Brookley Expansion Area and Gulf Disposal Plan No. 1 except that maintenance material from the lower bay, south of the intersection of the Theodore Channel, would be disposed in Mobile Bay adjacent the channel in areas currently utilized for maintenance dredged material disposal.

4. The Channel Widening Plan (least environmental damaging plan) which differs from the preceding plans primarily in that it considers only channel widening of the main bay channel to reduce delays due to periodic constrained one-way traffic. New work and annual maintenance material would be transported to a gulf disposal area.

* Plan test value minus test value.
6.08 The No Action Plan would involve no change in the existing authorized navigation channels for Mobile Harbor. There would be a continuation of existing conditions with no solution for present or future navigation problems. An analysis of this alternative shows that more than 17 million dollars a year as an average over the period of analysis would be lost from traffic delays. Since the present trends in deep draft shipping are toward use of larger vessels, the existing and projected problems could be expected to become more acute. In the absence of changes to the existing project, future maintenance would continue to be performed according to the current practice. The river channel disposal areas would reach capacity within the next 18 years and severe environmental constraints retard further development of on-land disposal areas in the vicinity. Disposal of material dredged from the bay channel would continue to disrupt benthos within the disposal areas, however, the impact is considered to be relatively minor and within the resiliency of the estuarine system provided that existing circulation patterns are not altered. The open water disposal operation would also continue to cause a short-term increase in turbidity, temporary reduction in dissolved oxygen levels near the discharge, and minor localized increase in heavy metals and nutrient related constituents. The Environmental Protection Agency would have to establish site designation for offshore disposal of the bar channel maintenance material which is presently being placed in an interim approved site.

6.09 The Brookley Expansion Area and Gulf disposal plan No. 1, the proposed plan, would enhance the possibility of economic development in the area as a result of lowered shipping costs and the creation of an additional parcel of prime area for industrial or harbor terminal uses. Environmental impacts of this plan are discussed in detail in Section 4 of this EIS and Section D of Appendix 5.

6.10 The total Gulf disposal plan would avoid the environmental losses associated with the Brookley Expansion area at the expense of further degradation to the offshore disposal area. However, acceptable offshore disposal areas could be designated through application of the section 103 guidelines as would be the case with the proposed plan. More energy would be required to implement this plan than any other channel deepening alternative considered, and the land enhancement benefits associated with the Brookley disposal area would be foregone.

6.11 The Brookley Expansion Area and Gulf Disposal Plan No. 2 is the economical means to meet the navigation needs of the area. Environmental impacts of this plan would be identical to those of the proposed plan except for the impacts related to disposal of maintenance material from the lower bay. At intervals of two to three years approximately 12,000 acres of lower bay bottom adjacent to the main ship channel would receive dredged maintenance material. This technique is presently employed for maintenance of the existing project. The 55-foot level of development as proposed would increase the average annual quantity of material dredged from the lower bay by about 150,000 cubic yards. Thus a total of about 2.7 million cubic yards of maintenance material would be disposed adjacent to the channel annually.
6.12 The most significant concern about disposal of larger quantities of maintenance material in the lower bay would be associated with the physical fate of the material. Evaluation of previous disposal in the bay indicate that for the period of record, 1960 to 1976, approximately 49,600,000 cubic yards of dredged material were disposed in the lower bay including 13,000,000 cubic yards of material from channel modifications. Bathymetric surveys of the disposal areas indicate that there has been a relatively small amount of accumulation of the material. Judging from this information it is expected that the increased quantities of maintenance material would also tend to be redistributed by wind, wave, currents, tidal action, or fisheries activities. As discussed under the "No Action Plan" in Section D of Appendix 5, studies to date indicate that the present practice of disposal of maintenance material adjacent to the channel results in a relatively minor biological impact considered to be well within the resiliency of the estuarine system. It is uncertain how the increased quantities of maintenance material would affect the biological integrity of the bay. Further studies would have to be conducted to implement this alternative. Due to the environmental acceptability of gulf disposal over bay disposal this alternative has been dropped from further study.

6.11 With the Channel Widening Plan, considered to be the least environmentally damaging plan, the main bay channel could be economically justified for a width up to 450 feet. Approximately seven million cubic yards of new work material would be removed to an EPA approved gulf disposal site along with about 4.2 million cubic yards of maintenance material annually. The removal of all new work and maintenance material from the bay to the gulf would have a positive impact to the study area since the plan would aid in retarding the filling of the bay. The resulting losses at the gulf disposal area are not quantified, but the technique of disposal is considered more environmentally acceptable. As discussed in paragraphs 4.36 through 4.41 studies to date indicate that there are suitable sites available for offshore disposal of the material.

6.14 During the public meetings and work level conference held in connection with the survey studies various environmental agencies suggested alternatives to mitigate environmental damages resulting from any plan to modify the Mobile Ship Channel. These alternatives include (1) restore tidal action in Chacaloochee and Polecats Bays, (2) restore circulation in Garrows Bend, (3) establish oyster beds in Bon Secour Bay, (4) improve water circulation in Mobile Bay by creating openings in ridges parallel the channel from Dog River to Mobile River, (5) fill depressions which exist in Mobile Bay, and (6) establish a recycle plan to remove material from existing Blakely and Pinto Island disposal areas.

6.15 Since any structural alternative would remove shallow water bottom from production, this has been considered an important aspect of any mitigation attempted. Chacaloochee Bay was effectively removed from interaction with

Appendix 1
Mobile Bay by construction of the Mobile Delta causeway. Tidal exchange is restricted to four 10x5-foot culverts passing under the highway. In order to provide full tidal flushing, almost the entire causeway across its mouth would require bridging. This may not be desirable for environmental reasons since the bay presently is heavily used by both sportfishermen and duckhunters. However, provisions for a partial restoration of tidal exchange would retard the rate of filling of the bay, provide a degree of control of undesirable aquatic plants, Eurasian milfoil, along the northern boundary of the causeway, and restore much of the nursery value of the lower bay. This measure could be implemented without additional model studies if the differing goals of the freshwater sportsman and the estuarine advocate could be resolved.

6.16 Construction of a causeway connecting McDuffie Island to the mainland has formed a barrier significantly hindering circulation in the Garrows Bend area. Construction of the Brookley Expansion area may further contribute to the localized circulation problems. Bridging the causeway would provide an opening to enhance river and tidal flushing in the area. This measure could be implemented without further model tests.

6.17 The establishment of oyster beds in Bon Secour Bay is not considered to be a desirable mitigation measure at this time, since the bay has a historical record of very poor spatfall. Thus, it is doubtful that any reefs established would be self-maintaining. However, the circulation changes which would be induced by channel enlargement and deepening could greatly enhance this potential. Additional study would be required as a part of post-authorization studies.

6.18 Efforts to alter existing circulation patterns by opening channels in the upper bay or by filling the depression on the eastern side of the ship channel are viewed with reservation. Such actions have the potential of changing the long-term water quality of the bay in a positive manner. However, on the other hand, a certain amount of oxygen depletion is required if "jubilees" on the eastern shore are to continue. When the impact on larval forms is considered, "jubilees" may not be a bonanza as is commonly thought. Further investigation would be necessary during post-authorization studies.

6.19 A methodology to extend the useful life of the upper bay disposal areas has been developed by the Waterways Experiment Station. Although the plan does not provide for the removal of material to the gulf, it is the first step toward implementation of this technique in latter years. The method consists of a dewatering technique. The Mobile District has already purchased a riverine utility craft which will be used to prevent crust formation and to dewater the areas. Utilizing this technique, the Pinto Island area can be used for the next 18 years. It is presently not economically feasible to haul the material to the gulf for disposal.
6.20 Another alternative is the feasibility of establishing wetland areas as provided under section 150 of PL 94-587. The southern portion of the upper bay disposal area would be suitable for marsh growth and a marsh establishment program would be included with the recommended plan as a mitigation measure for the loss of about 70 acres of marsh along the existing Brookley shoreline. Further investigations for section 150 establishment of wetlands are being conducted as a part of the existing maintenance program for the Mobile Harbor channel.
7.01 Relationship Between Local Short-Term Uses of Man's Environment and the Maintenance and Enhancement of Long-Term Productivity. Implementation of the project would enhance the long-term productivity of the area by providing more efficient port facilities for industrial development and by ensuring Mobile's continued importance as a port through the maintenance of desirable regional growth. Construction of the project would encourage additional industrial growth in the vicinity of the Brookley Expansion area. It would result in some land use changing from residential to industrial. This trend can be expected to occur with or without the project and will change the long-term use of the area.

7.02 A decrease in long-term biological productivity in the bay and nearshore area would occur as a result of the commitment of water bottoms occupied by the channels and disposal areas. A long-term increase in biological productivity would occur due to discontinued open water disposal of maintenance material in the bay. Construction of the upper bay expansion area would also provide for the creation of marsh and waterfowl habitat. The overall tradeoffs will be assessed through further studies of the bay and offshore areas.
8.01 **Any Irreversible and Irretrievable Commitments of Resources Which Would be Involved in the Proposed Action.** Implementation of the project would commit bay and nearshore water bottoms to the enlarged channels and disposal areas. There would be an irretrievable commitment of the aquatic organisms destroyed during construction of the channels and disposal areas. The labor, materials, and energy necessary for construction and maintenance activities would also be irretrievable.
9.01 COORDINATION WITH OTHERS. An initial public meeting for the study was held on 25 April 1967 for the purpose of informing the public about the study and to obtain their views as to desired modifications to the existing project for Mobile Harbor. The meeting was attended by 72 persons representing Federal, State, county, and local government agencies and other civic bodies, navigation interests, industry, and local interests concerned with port development.

9.02 Proponents at the meeting requested that the Federal project for Mobile Harbor be modified to include adoption and construction of the Theodore Channel to provide a channel 40 feet deep and 300 feet wide and that such channel be extended by land cut into a turning basin within the Theodore Industrial Park. Local interests further requested that the turning basin opposite Magazine Point in Mobile River be enlarged and that an anchorage basin of sufficient size to accommodate 12 large ocean-going vessels be provided near the mouth of Mobile River. They also requested that the Corps of Engineers initiate such studies as necessary to determine the engineering and economic feasibility of providing a 50-foot depth in the Mobile Harbor channels. No opposition was expressed to improvement of the harbor, however, the Mobile County Wildlife and Conservation Association requested that all possible steps be taken to minimize adverse effects of dredged material disposal on fish and wildlife.

9.03 Study efforts were directed for the next several years to the authorization and advanced engineering and design studies for the Theodore Ship Channel. Coordination for that study is discussed in the Final Environmental Impact statement for the project which was filed with the Council on Environmental Quality on 10 March 1977.

9.04 Early in 1975, a special committee which became known as the Mobile Harbor Advisory Committee was formed for the purpose of providing access to the planning process for a wide cross-section of the various public in the Mobile Region. Membership on the committee was comprised of individuals from the following interest groups: citizens, business and commerce, local government, environmental interests, state government, port interests, organized labor, and fish and wildlife interests. Several workshop meetings were held with this committee during the major stages in plan formulation. This committee served a vital role to access the public response to alternative plans and to provide a public contact point through key stages in the plan formulation process.

9.05 A second public meeting was held at Mobile, Alabama on 22 November 1976 with over 140 persons in attendance. Alternative plans were presented for the disposal of dredged material, both for the new work and maintenance material which would result from the implementation of any channel improvement. All alternatives considered at this stage of the planning process were related to a 50-foot, deep-draft channel with commensurate widths, anchorage basins, turning areas, and auxiliary barge and access channels. State officials, representatives of shipping interests, and local citizens either spoke or wrote letters in favor of the project. Few of these speakers addressed their comments to the purpose of the meeting which was the
discussion of proposed alternatives for deposition of dredged material. The majority of persons either did not address the question altogether or left the selection decision to the Corps of Engineers and directed their remarks to the economic necessity of expediting the project. Those who did address the topic endorsed the Breckley Expansion plan as the most desirable.

9.06 Federal and State agencies, environmental groups, and local citizens spoke or wrote letters expressing concern or opposition, related to the project or certain dredged material disposal alternatives. Concerns included the necessity or desirability of deepening Mobile Ship Channel, the potential environmental degradation of the bay and environs and the possibility of invalidating the Mobile 208 studies being conducted to determine the optimum location of waste discharge points within the bay. The Environmental Protection Agency, although not taking an adverse stand to further development of Mobile Harbor, in general sums up the views of those opposed. This agency prefers that the dredged material be transported to an approved disposal site in the Gulf of Mexico. Also, open water disposal in the bay from both new work and maintenance dredging should be discontinued and spoil island development and navigational channel improvements should be supported by data generated not only from a mathematical model but also from the existing physical bay model.

9.07 In addition to the public meetings and workshops, informal working level meetings were conducted with various environmental agencies and an environmental quality (EQ) committee to identify problems and needs of the area and to develop measures to enhance environmental quality. Most input from the EQ committee involved broad research efforts, beyond the scope of these survey study investigations, to gain a better understanding of the Mobile Bay system. Suggestions from the local scientific community included:

1. Complete, bay wide, bathymetric survey at a 1,000-foot resolution
2. More dependable suspended sediment and bed load sediment data inorder to calculate accurately the sediment budget
3. Flushing time characteristics over the entire range of river discharges
4. Bay wide circulation characteristics; particularly in need are bottom current measurements
5. A real attempt to establish a dissolved oxygen budget
6. Natural and man-made product chemistry systems. Complete budget studies
7. Virology starting with the very basics
(8) Bacteriology with particular emphasis on dredging activities (resuspension of bacteria and/or nutrients)

(9) The response of marshes to natural and man-made stresses.

(10) Benthic aquatic plant inventory and response to natural and man-made stresses

(11) The entire area of food chains

(12) Commercial and sports aquatic animals; additional information on population dynamics, life histories, growth, mortality, etc.

The environmental agencies developed a list of environmental quality objectives which included:

(1) Establish oyster beds in Bon Secour Bay

(2) Improve water circulation in Mobile Bay by creating openings through existing disposal area ridges or remove the ridge completely from Dog River to Mobile River. Construct openings through causeways to improve water circulation. Fill depressions which exist in Mobile Bay.

(3) Test circulation recommendations on model at Vicksburg.

(4) Establish a recycle plan to remove material from the existing Blakely Island and Pinto Pass disposal areas. All of these suggestions have been considered and incorporated into the study where possible.

9.08 After distribution of the Draft Technical Report and Draft EIS, a third public meeting was held at Mobile, Alabama, on 31 July 1979 with 209 persons in attendance. The last phase of planning and study results was summarized at the meeting. The main comments made by the environmental agencies and interests are summarized as follows:

(1) Opposed to further loss of bay bottom by constructing the Brookley Expansion Area.

(2) Disposal in Mobile Bay would increase suspended solids concentrations.

(3) Construction of the Brookley Expansion Area would degrade the aesthetic value of the adjacent University of South Alabama property.

(4) Part of the Brookley Expansion area should be set aside for recreational purposes such as an urban waterfront park.

(5) Construction of the Brookley Expansion area might nullify 208 study results since filling would reduce the assimilative capacity of Mobile Bay.
(6) Larger ships in the bay will cause increased erosion problems.

(7) Recreational usage of Mobile Bay not sufficiently addressed.

(8) Commercial seafood industry not adequately included in b/c ratio.

(9) Mitigation by purchase of lands, i.e., Little Point Clear and Three Rivers.

(10) Need to address offshore port-handling facility with slurry pipeline.

(11) Suggested a trial period for dumping dredged material in Gulf.

(12) EIS should be written by independent third party.

(13) Prefer total Gulf disposal plan.

(14) Additional model studies should be conducted.

(15) Should have mitigation for previous damages to Mobile Bay.

(16) New work material should be used to rebuild Sand Island.

(17) Further, the US Fish and Wildlife Service favored the channel widening and Gulf disposal plan with mitigation included in the authorization. The Environmental Protection Agency expressed concern about the impacts to water quality from channel construction, loss of wetlands and bay bottom, and degradation of air quality from increased industrialization. They suggested that additional model studies be conducted and all new work and maintenance material be disposed in the Gulf of Mexico.

All of these comments were taken into consideration for finalization of the Report and EIS.

9.09 On 20 May 1980 the US Fish and Wildlife Service submitted a report (Appendix 4) in accordance with the Fish and Wildlife Coordination Act of 1958, as amended. Conclusions and recommendations of the report are summarized as follows:

1. Environmental Quality Plan

   a. Land should be acquired and managed to maximize fish and wildlife benefits.

   b. Areas that have low fish and wildlife potential should be selected for port expansion purposes.

   c. Water circulation between Mobile Bay and Delta could be improved by creating openings in the caseways.
d. Water quality within Mobile Bay could be improved by providing better circulation through cuts or removal of spoil levees along the existing navigation channel.

e. Environmentally-sound areas for disposal of dredged material should be designated. This would include deep-gulf sites and non-wetlands of low fish and wildlife value.

2. Recommendations

a. The filling of bay bottoms and wetlands should be deleted from the selected plan.

b. Unless more environmentally-sound disposal areas are identified, dredged material should be taken to approved deep gulf sites.

c. Studies should be conducted to identify environmentally-sound areas for port expansion.

d. An environmental quality plan should be developed in accordance with Principles and Standards.

e. Water quality within Mobile Bay could be improved by providing better circulation through cuts or removal of spoil levees along the existing navigation channel.

9.10 Two of the above requests have not been met through the US Army Corps of Engineers study efforts. The first pertains to the acquisition of lands to maximize fish and wildlife benefits. Since this proposal is not directly related to project impacts or in-kind mitigation, it is considered inappropriate to include it with the recommended plan. The other item, construction of the Brookley Expansion area with loss of bay bottom and wetlands, is a feature of the recommended plan which most environmental agencies and interests oppose. Total gulf disposal is their preferred alternative. It is also the choice of disposal for the Corps EQ plan (least environmentally-damaging plan). However, unlike the environmental agencies and groups, the US Army Corps of Engineers, under Principles and Standards, must take into account economic and other factors including environmental concerns in plan development.

9.11 The draft environmental impact statement, filed with the President's Council on Environmental Quality on 13 July 1979, was mailed to Federal, State, and local agencies and other parties on 2 July 1979. Copies of letters of comment received during coordination of the DEIS and responses are contained in Appendix 3. Responses to the comments are presented on the page facing each letter and responses are keyed to comments by number. Comments on the DEIS generally are the same as those outlined in above paragraphs. One local group, the Mobile Bay Audubon Society, failed to submit comments on the DEIS,
but have otherwise expressed their concern over the proposed project through other written correspondence, statements at public meetings, and participation on the EQ committee and technical advisory groups. Their comments are included in above paragraphs and are similar to most environmental concerns expressed in Appendix 3.

SECTION 404(b) EVALUATION
1. PROJECT DESCRIPTION - The proposed plan for channel improvements to Mobile Harbor involves construction of a disposal area in Mobile Bay in the vicinity of the Brookley waterfront as shown on figure 2 of the Final Environmental Statement (FEIS) (Appendix 1) for the project. As such, it must be evaluated in accordance with the 5 September 1975 guidelines promulgated by the Environmental Protection Agency pursuant to Section 404(b), PL 92-500, for disposal of dredged or fill material into navigable waters of the United States.

a. Description of the Proposed Discharge of Dredged or Fill Materials:

   (1) General Characteristics of the Material - In 1974 the Mobile District Corps of Engineers collected surface layer and sediment core samples from along the alignment of the Mobile Ship Channel. Results of the sediment analyses are presented in the FEIS and sections B and D of Appendix 5. Physically, the sediments are predominantly sand in the northern third of the bay channel from the mouth of the Mobile River southward for about 6.5 miles. The next 6 miles of channel down to the intersection of the Theodore Channel contains material composed of gray clay of high plasticity (fat clay) with occasional lenses of gray sandy clays and silty sands. From a chemical standpoint, concentrations of all parameters analyzed are generally higher in the clay, silty-clays, and clayey silts rather than the sand or silty sand. The concentrations of the chemical constituents generally appear to increase with distance south of the mouth of Mobile River. With respect to depth, the overall average concentrations of the deeper sediments of the ship channel were less than that of the surface layer sediments.

   (2) Quantity of Material Proposed for Discharge - Approximately 39,630,000 cubic yards of new work material from the upper bay channel is sandy and about 23,770,000 cubic yards is clayey material.

   (3) Source of the Material - Material will be dredged from the Mobile Ship Channel beginning near the mouth of the Mobile River and proceeding to about the intersection of the Theodore Ship Channel. The sandy new work material from the upper bay would be used to construct the dikes and fill approximately 61 percent of the Brookley expansion area. This would provide 1,047 acres of fastland to an elevation approximately 17.5 feet above mean low water. The remainder of the fill area would accommodate approximately 24 million cubic yards of new work material (clay) from the next 6 miles of channel down to the intersection of the Theodore Channel.
b. Description of the Proposed Disposal Site for Dredged or Fill Material:

(1) Location - The disposal area is shown on Figures 1 and 2 of the FEIS for the project.

(2) Type of Disposal Site - Approximately five million cubic yards of the sandier new work material would be disposed in open water for construction of the dikes for the disposal area. The remaining 58,400,000 cubic yards of material would be disposed within the confines of the diked disposal area.

(3) Method of Discharge - The material would be placed in the disposal area by means of a hydraulic pipeline dredge.

(4) When Will Disposal Occur - The time for initiation of disposal would be determined by construction scheduling, and is not now determined. Construction of the proposed project could be accomplished in about seven years.

(5) Projected Life of the Disposal Site - The site will be used for disposal of dredged material during construction only. After a period of settling, a portion of the disposal area will be utilized for port development.

(6) Bathymetry - The area is relatively shallow and ranges from four to six feet in depth, except for two deep holes. The area constitutes approximately five percent of the bay's bottom that is less than six feet deep.

2. PHYSICAL EFFECTS

a. Potential Destruction of Wetlands - Effects on:

(1) Food Chain Production - The Brookley Expansion area will abut an existing man-made fill area. This area is characterized by about 70 acres of marsh which has voluntarily established along the shoreline. Plant species mainly include Panicum sp., Phragmites communis (common reed), Hydrocotyle umbellato (Pennywort), Iva frutescens (marsh-elder), Myrica cerifera (wax myrtle), Quercus nigra (Water Oak), Zizania aquatica (wild rice), Spartina patens (salt meadow hay), Silax nigra (black willow), Cladium jamaicense (sawgrass), Baccharis halimifolia (groundsel tree), Typha latifolia (common cat-tail), Daubentonia punicea, and Pinus sp. A large part of the wetlands area has been significantly disturbed by trash dumping and fill activities. Construction of the Brookley Expansion area disposal site would eliminate this wetland area. The recommended plan provides for a marsh establishment program which will affect the wetlands loss.
(2) **General Habitat** - Disposal within the marsh and water areas would affect the habitat for invertebrate and vertebrate estuarine animals including several species of polychaete worms, clams, snails, isopod and amphipod crustaceans, grass shrimp, blue crabs, commercially valuable shrimp, hermit crabs, catfish, menhaden, anchovy mullet, flounder, croaker, and others of the marine, brackish, and freshwater vertebrate found in the area. Impacts of this loss are further discussed in section 4 of the FEIS.

(3) **Nesting, Spawning, Rearing and Resting Sites for Aquatic or Land Species.** The marsh and water areas represent suitable spawning and nursery habitat for many of the species discussed under "General Habitat."

(4) **Those Set Aside for Aquatic Environment Study or Sanctuaries or Refuges - Not applicable.**

(5) **Natural Drainage Characteristics** - Natural drainage characteristics have been altered by previous fill and other development activities in the area. The proposed disposal area would not be expected to have significant adverse effects on drainage characteristics of the area.

(6) **Sedimentation Patterns - Not significant.** The area adjacent to the western side of the main ship channel in the vicinity of Brookley is presently characterized by a dredged material disposal mound which was created in the early 1960's by disposal of new work material from channel modifications. This mound, paralleling the main ship channel, is emergent or nearly so for more than the full length of the proposed Brookley Expansion area. The expansion area dikes would be built generally along the alinement of the existing disposal mound, and thus, would not be expected to significantly affect circulation or sedimentation patterns of the area. Also, the shadowing effect of McDuffie Island, to the north, would tend to lessen the possibility of the Expansion area affecting circulation. This conclusion is in agreement with the results of model studies which show the same general changes in salinity for the upper bay with or without the Brookley Expansion area.

(7) **Salinity Distribution - Not significant, see paragraph 2.a.(6) above.**

(8) **Flushing Characteristics - Not significant, see paragraphs 2.a.(5) and (6) above.**

(9) **Current Patterns - Not significant, see paragraph 2.a.(6) above.**

(10) **Wave Action, Erosion or Storm Damage Protection - Not significant.** The existing shoreline for the Brookley area is characterized by a narrow beach type area and the above described marsh. The proposed diked disposal area would be protected by riprap and marsh.

(11) **Storage Areas for Storm and Flood Waters - Not significant due to the small portion of the bay to be filled.** Any storage area provided by the existing marsh would be replaced by the proposed marsh establishment.
(12) **Prime Natural Recharge Area** - Not applicable.

b. Impact on Water Column:

(1) **Reduction in Light Transmission** - The disposal operation would increase turbidity and suspended solids concentrations over a large area of the bay during the period of construction and stabilization of the dikes which may involve a period of several years. Impacts of turbidity are discussed in detail in section 4 of the FEIS. Due to the naturally turbid conditions of the estuary, a normally low phytoplankton community, and significant submerged grass beds being far removed from the area of influence turbidity impacts will be minimal. Utilization of sand material for dike construction will tend to minimize turbidity. Also, methods are available for reducing turbidity and will be considered further during post-authorization studies for the plan. After completion of the dike construction, the remaining new work material from the upper bay would be placed within the confines of the expansion area. Water discharged through the weirs of the diked disposal area may cause a short-term increase in turbidity in the receiving waters. The impact will be minimized by controlling the weir structures to provide retention times sufficient to permit the settling of small particles.

(2) **Aesthetic Values** - The turbidity associated with the open-water dike construction would be aesthetically displeasing to some people. However, as noted in paragraph 2.b.(1) turbidity will be minimized to the extent practicable. The elevated disposal areas as opposed to the open-water area may also be aesthetically displeasing. Establishment of marsh grasses on the disposal area and grassing the side slopes could alleviate the problem.

(3) **Direct Destructive Effects on Nektonic and Planktonic Populations** - As discussed in section 4 of the FEIS, construction of the Brookley expansion area will destroy the nektonic and planktonic populations associated with the existing water area. After stabilization of the dikes is achieved, nektonic and planktonic populations of the area surrounding the disposal site should return to normal levels. This component of the bay ecosystem has been shown to have a high resilience to disturbance.

c. **Actual Covering of Benthic Communities**:

(1) **Actual Covering of Benthic Communities** - Benthic habitat within the 2.7 square miles committed to the disposal area will be permanently lost and an additional 2.0 square miles of habitat could be temporarily disrupted by mud flows from the dredge discharge. The expansion area will be located in a part of the bay that is considered to be least sensitive to increased additional human disturbances to the benthic community. A bay usage study will be conducted during post-authorization studies to better define biological productivity, gather water quality data, and predict recreational potential for various sections of the bay. This will provide a better comparative analysis of the impacts of the bay disposal operations.
(2) **Changes in Community Structure or Function** - The benthic community located within the expansion area will be completely destroyed by the disposal operation. The aquatic system will be replaced by an upland and wetland system. Areas affected by mud flows would be expected to repopulate within a normal growth season after disturbance.

d. **Other Effects:**

(1) **Changes in Bottom Geometry and Substrate Composition** - The aquatic bottom within the proposed disposal site composed of silty sand, clayey silt, and sand-silt-clay mix will be converted to an on-land area composed of sand and clay materials.

(2) **Water Circulation** - Construction of the disposal area may add to the poor circulation conditions of the Garrows Bend area. A mitigating feature to improve water circulation in the area would be to construct an opening in the causeway connecting McDuffie Island with the mainland. Mitigating features will be addressed further during post-authorization.

(3) **Salinity Gradients** - Although model studies show that modifications to the ship channel could cause extensive changes in the salinity patterns of the bay, construction of the disposal area would not be expected to significantly affect salinity gradients, see paragraph 2.a.(6) above.

(4) **Exchange of Constituents between Sediments and Overlying Water with Alterations of Biological Communities** - The exchange of constituents between the sediments and the overlying water would not be expected to significantly alter biological communities due to the sandy nature of the material to be used for dike construction.

3. **CHEMICAL - BIOLOGICAL INTERACTIVE EFFECTS**

a. **Does the Material Meet the Exclusion Criteria?** Material for the dike construction meets the exclusion criteria since it is composed predominantly of sand. All other material would be placed within the confines of the diked disposal area. However, elutriate tests have been performed for the proposed dredged material, see paragraph 3.b.

b. **Water Column Effects of Chemical Constituents:** As discussed in section 4 of the FEIS, a number of detailed studies have been conducted in Mobile Bay over the past decade evaluating the effects of open-water disposal of dredged material. Some of the more recent studies have utilized the elutriate and bioassay techniques of analysis as well as field tests. Results of the studies indicate that any release of pollutational constituents to the water column would be expected to be transitory and limited to the immediate vicinity of the discharge point. Lee, et al (1978) concluded that the relatively rapid dispersion of any released contaminants at the disposal site creates a situation where the likelihood of significant toxicity or bioaccumulation of contaminants present in the dredged sediments is very small.
c. Effects of Chemical Constituents on Benthos: See paragraphs 3.a. and b.

4. DESCRIPTION OF SITE COMPARISON

   a. Total Sediment Analysis: A comparison of the chemical constituents of the sediment at the dredging site with sediment at the disposal site is not considered necessary because of the sandy nature of the material to be used for dike construction and the fact that the remaining material will be disposed within the diked area.

   b. Biological Community Structure Analysis: See paragraph 2.c.(1).

5. REVIEW APPLICABLE WATER QUALITY STANDARDS

   a. Compare Constituent Concentrations: Dredged material would be placed in water classified for Fish and Wildlife by the Alabama Water Quality Standards. Under this classification excessive fecal bacteria and sewage contamination are prohibited. Material discharged must not cause the pH to deviate more than one unit from the normal or natural pH nor be less than 6.5 nor greater than 8.5. Normal daily and seasonal temperature must be maintained and dissolved oxygen concentrations must not be less than 5 mg/l except in dystrophic waters or where natural conditions cause the value to be depressed. Turbidity must not exceed 50 Jackson units above background. Background is interpreted as the natural condition of the receiving waters without the influence of man-made or man-induced causes. Turbidity levels caused by natural runoff are included in establishing background levels. In making any tests or analytical determinations to determine compliance or non-compliance with water quality criteria, samples shall be collected in such manner and at such locations approved by duly authorized members of the Alabama Water Improvement Commission as being representative of the receiving water after reasonable opportunity for dilution and mixture of the wastes discharged thereto.

   b. Consider Mixing Zone: A mixing zone is not considered to be a critical factor due to the sandy nature of the material to be used for dike construction. Since the remaining material will be disposed within the confines of the diked area, chemical constituents can be maintained at acceptable levels at the boundary of a very small mixing zone. See paragraphs 3.a. and b.

   c. Based on a. and b. above will the Disposal Operation be in Conformance with Applicable Standards? Yes

6. SELECTION OF DISPOSAL SITES FOR DREDGED OR FILL MATERIAL

   a. Need for the Proposed Activity: The proposed plan would enhance the possibility of economic development in the area as a result of the lowered shipping costs and provide a safer navigation channel. Construction of the disposal area would provide a prime area for industrial or harbor terminal uses.
b. Alternatives Considered: As discussed in Section D of Appendix 5 and section 6 of the FEIS, a number of dredged material disposal options were considered as part of the plan formulation studies. Basically the structural alternatives include: 1) no action, 2) construct island or fill areas in upper and lower Mobile Bay, 3) open-water disposal in bay and/or gulf, 4) upland disposal, 5) recycle material off existing disposal sites, and 6) abate shore erosion with dredged disposal material.

c. Objectives to be Considered in Discharge Determination:

(1) Impacts on Chemical, Physical, and Biological Integrity of Aquatic Ecosystem - See paragraphs 2.c.(1, 2 and 3.a., b.

(2) Impact on Food Chain - See paragraphs 2.c.(1), 2 and 3.a., b.

(3) Impact on Diversity of Plant and Animal Species - Not significant

(4) Impact on Movement Into and Out of Feeding, Spawning, Breeding and Nursery Areas - The proposed disposal site is presently used for sportshrimping and the shoreline furnishes recreational opportunities including softshell crabbing, castnetting for mullet and floundering. The area is considered to have nursery value, especially for shrimp.

(5) Impact on Wetland Areas Having Significant Functions of Water Quality Maintenance - Not applicable.

(6) Impact on Areas that Serve to Retain Natural High Water or Flood Waters - Not significant since the disposal site represents such a small portion of the total bay and delta area.

(7) Methods to Minimize Turbidity - Turbidity will be minimized by use of sandy material for the dike construction. Other methods to minimize turbidity include silt screens, modification of the pipeline configuration at the discharge point or the use of a submerged diffuser system. These will be looked at further during post-authorization studies. The diked disposal area will be sized to provide enough ponding to reduce turbidity.

(8) Methods to Minimize Degradation of Aesthetic, Recreational, and Economic Values - See paragraphs 2.b.(2) and 2.c.(1).

(9) Threatened and Endangered Species - Implementation of the proposed project is not expected to have significant detrimental effects on threatened fish and wildlife which may appear in the area. All of the construction activities within the bay will be in areas that have been subject to disturbance by periodic maintenance dredging, dredging for fill, or port-related activities. This conclusion has been confirmed through coordination with the US Fish and Wildlife Service. See Appendix 3, Public Views and Response.
(10) Investigate Other Measures that Avoid Degradation of Aesthetic, Recreational, and Economic Values of Navigable Waters - See paragraphs 2.b.(2) and 2.c.(1).

d. Impacts on Water Uses at the Proposed Disposal Site:

(1) Municipal Water Supply Intakes - No municipal water supply intakes are expected to be affected by disposal of the dredged material.

(2) Shellfish - The upper area of the bay is permanently closed to oyster shell fishing. The dominant benthic organism in the vicinity of the proposed disposal area is the brackish water clam, *Rangia cuneata*. The disposal operation would destroy a large percentage of the populations of the area.

(3) Fisheries - Suspended sediments may be of harm to zooplankton, fishes, and motile invertebrates. Several studies suggest that suspended particles raised by dredging have no gross effects on the diversity or abundance of zooplankton nor the composition of fish eggs and larvae (Dovel, 1970; Goodwyn, 1970). However, other investigations indicate that periodic resuspension of silts and clays by repeated dredging or wind and wave action may adversely affect the general metabolism and metamorphosis of fish eggs and larvae as well as other developmental stages (Sherk, 1971, and 1972; Livingston, et al, 1972).

Turbidity and suspended material may affect fishes directly or indirectly. Direct effects, according to Stern and Stickle (1978), could include lethal agents and those factors that influence physiological activities (reproduction, growth, development) or produce abrasive wear on tissue. Indirect effects include modifications to habitats and food chain organisms. Recent data, based upon weight/volume concentrations of suspended solids, from several closely monitored laboratory studies are probably more indicative of natural responses of adult fishes to suspended solids (Stern and Stickle, 1978). The results of these studies have indicated that adult fishes, as well as invertebrates, are affected by a complex interaction between suspended solids, temperature, and dissolved oxygen. A correlation exists between normal habitat and sensitivity to suspended solids with the most tolerant species being the bottom dwellers while the filter feeders are the most sensitive. High suspended solids would be less harmful in winter than in summer and fishes as a group are more sensitive to suspended solids than many of the invertebrates studied to date.

Based on Stern and Stickle (1978) and studies conducted in D'Olive Bay, Alabama, by Vittor (1974), most fishes usually migrate out of the dredging area and gross effects to fishes are rarely observed. Patterns of seasonal occurrence, abundance, species diversity, and conditions of the gill filaments among fishes exposed to dredged operations and dredged material disposal generally remained unchanged. Under normal circumstances fish avoid turbid waters and have the ability to clear membranes of accumulated silt upon entering undisturbed water. Most studies have indicated that upon exposure to temporary increases in turbidity and suspended material similar to that encountered in areas where dredging or the disposal of dredged material has occurred no permanent effects were exhibited. Also see paragraph 6.c.(4) and section 4 of the FEIS.
(4) **Wildlife** - Not applicable.

(5) **Recreation Activities** - See paragraph 6.c.(4).

(6) **Threatened and Endangered Species** - See paragraph 6.c.(9).

(7) **Benthic Life** - See paragraphs 2.c.(1), (2).

(8) **Wetlands** - See paragraphs 2.a.(1), (2).

(9) **Submersed Vegetation** - No significant submersed grass beds would be affected by the disposal operation.

(10) **Size of Disposal Site** - The disposal site will be confined to the smallest practicable area.

(11) **Coastal Zone Management Programs** - As a result of Federal and State legislation, Alabama has developed a coastal zone management program under the direction of the Coastal Area Board. By letter of 12 May 1980, the Coastal Area Board concluded that the recommended plan and all alternatives are consistent with their management program, provided that biological resources are protected to the maximum extent practicable and appropriate mitigation measures are implemented. Items of concern have been adequately addressed in the FEIS.

  e. **Conditions to Minimize Harmful Effects:**

  (1) **Water Quality Criteria** - Water quality problems are not expected during dike construction since the material is predominantly sand. All other material will be confined except for minor amounts of suspended solids which will escape over the weirs.

  (2) **Investigate Alternatives to Open-Water Disposal** - See paragraph 6.b.

  (3) **Investigate Physical Characteristics of Alternative Disposal Sites** - See paragraph 6.b.

  (4) **Ocean Dumping** - Offshore disposal was considered and chosen as the most viable option for disposal of approximately 58,654,000 cubic yards of new work material from the lower bay and all future maintenance material from the entire project for a 50-year life.

  (5) **Where Possible, Investigate Covering Contaminated Dredged Material with Cleaner Material** - Not applicable.

  (6) **Investigate Methods to Minimize Effect of Runoff from Confined Area on the Aquatic Environment** - The weirs will be controlled to minimize turbidity from the disposal area. Side slopes of the disposal area will be protected with riprap and grass.

  (7) **Coordinate Potential Monitoring at Disposal Site With the Environmental Protection Agency** - Any monitoring activities conducted in conjunction with construction of the project will be coordinated closely with the EPA.
7. **STATEMENT AS TO CONTAMINATION OF FILL IF FROM A LAND SOURCE**

The riprap will be uncontaminated stones.

8. **DETERMINE MIXING ZONE**

See paragraphs 2.b.(1) and 5.b. A mixing zone has been determined for the dike construction using the procedures specified in the Waterways Experiment Station (WES) Technical Report DS-78-13, "Prediction and Control of Dredged Material Dispersion Around Dredging and Open-Water Pipeline Disposal Operations." The mixing zone was determined only for an approximate "worst case" parameter, turbidity. The calculations were based upon a mathematical turbidity plume model utilizing estimated conditions of Mobile Bay during the disposal operation. This model provides an approximate shape and the dimensions of the plume. Factors such as discharge configuration, waves, and wind, although important, are not considered in the model due to their complex and quantitatively unpredictable effect on the plume characteristics. Results of the calculations indicate the plume will attain an ovoid shape with the dimensions approximately 1.3 miles in length by 0.3 miles at the widest point. Based upon the model, the suspended solids concentration at 1.3 miles from the discharge point would be approximately 50 mg/l.

9. **CONCLUSIONS AND DETERMINATIONS**

a. An ecological evaluation has been made following the evaluation guidance in 40 CFR 230.4, in conjunction with the evaluation considerations in 40 CFR 230.5.

b. Appropriate measures have been identified and incorporated in the proposed plan to minimize adverse effects on the aquatic environment as a result of the discharge.

c. Consideration has been given to the need for the proposed activity, the availability of alternate sites and methods of disposal that are less damaging to the environment, and such water quality standards as are appropriate and applicable by law.

d. Other alternatives are not practicable and the discharge into wetlands will not have an unacceptable adverse impact on the aquatic resources.

10. **FINDINGS.** I, therefore, find that the discharge sites for the proposed Mobile Harbor Channel Improvements project have been specified through the application of the Section 404(b) guidelines.

Date: 29 October 1980

Dear Mr. Green:

We have reviewed the Draft Environmental Impact Statement on the Channel Improvements to Mobile Harbor and have some reservations regarding the long-term environmental consequences of the proposed intrabay spoil disposal and subsequent fast land creation. We are concerned for the overall impact on water quality resulting from the deepened ship channel and open water dispersal of spoil. Further, the sacrifice of 1,710 acres of shallow water estuary bottoms in the upper bay for spoil disposal and fast land creation represents an important ecological loss. The peninsula formed by this disposal area may act like a groin to cause a backwater for additional deposition of solids coming down Mobile River.

The enlarged ship channel is going to affect certain hydrological and biological aspects of the bay by creating an enlarged and more dynamic salt wedge. Although the model tests conducted at Vicksburg did not represent the exact features of the proposed plan, the results indicated that salt water intrusion would extend further up the Mobile River while increasing the fresh water flow down the Tensaw River. The diversion of the present flow pattern could decrease the assimilative capacity in certain areas of both the river and the bay and lead to increased frequency of water quality standards' violations, causing an increase in the cost of waste water treatment at Mobile to meet these standards.

Additional problems would be caused by the change in the overall salinity distribution within Mobile Bay. Model tests indicate an increase in the salinities of the upper bay area with the greatest increases near the channel, decrease in the salinity of Bon Secour Bay and probable increases in the salinity of the lower bay west of the channel. The effect on oyster production in the lower bay cannot be accurately predicted from model studies; however, changes in salinity are known to impact shellfish production.
1. Your concerns are recognized and we feel that environmental impacts associated with project modifications, and appropriate mitigation measures, have been adequately addressed in the Report and FEIS to meet the decision-making needs. Items generally mentioned in your first comment are addressed in more detail in response to following specific comments.

We question your supposition that the upper bay disposal area "may act like a groin to cause a backwater for additional deposition of solids coming down Mobile River." The area adjacent to the western side of the main ship channel in the vicinity of Brookley is presently characterized by a dredged material disposal mound which was created in the early 1960's by disposal of new work material from channel modifications. This mound, paralleling the main ship channel, is emergent or nearly so for more than the full length of the proposed Brookley Expansion area. The expansion area dikes would be built generally along the alinement of the existing disposal mound, and thus would not be expected to significantly affect circulation characteristics of the area. Also, the shadowing effect of McDuffie Island, to the north, would tend to lessen the possibility of the expansion area affecting circulation. This conclusion is in agreement with the results of model studies which show the same general changes in salinity for the upper bay with or without the Brookley Expansion area.

2. Model tests show the enlarged channel would allow more of the high salinity gulf waters to travel northward through the bay and, thereby, increase the salt wedge intrusion in the river. This may slightly alter flows in the lower segment of the river and thus could affect the assimilative capacity of the area which presently experiences poor water quality conditions.

It is doubtful that enlarging the channel would lead to an increase in the cost for waste treatment since the Section 208 Water Quality Management Plan for Mobile and Baldwin Counties presently recommends attainment of best practicable treatment levels for industry in the area. However, alteration of flushing in Mobile River would be considered adverse. As expressed in the FEIS, further studies would need to be conducted to determine the degree of impact of the 55-foot deep channel and mechanisms for offsetting adverse effects.

3. All of these points are considered to be adequately addressed in the EIS and, as stated, further model studies would need to be conducted for the 55-foot deep channel.
We do not concur with some statements in the 404(b) evaluation and find other sections not fully addressed.

404(b) Evaluation

Page 2, 2. Physical Effects (a)(1). About 10 acres of wetlands habitat exist along the shore of the Brookley Expansion area spoil site while the contiguous shallow water areas are valuable nursery and feeding areas for shrimp, crabs and fish. Since the inception of the Mobile Harbor Project more than 2,000 acres of marsh and shallow water estuarine areas valuable for fish and wildlife habitat have been lost as spoil disposal sites in Polecat Bay and in the Blakely and Pinto Island areas. Approximately 1,280 acres of bay bottoms and 26 acres of marsh have been lost in the construction of the Theodore Industrial Project. Additional marsh and shallow water estuarine areas have been disrupted and degraded in the Dog and Fowl River areas.

The value of these marsh and estuarine areas is well recognized. In addition to providing valuable fish and wildlife habitat, the marsh filters and assimilates nutrients and pollutants, thereby improving water quality. It also produces the detrital material which forms the base of the food chain.

Page 4, d. Other Effects (3) Salinity Gradients

We disagree with the statement that "construction of the disposal area would not be expected to significantly affect salinity gradients." The salt wedge will occupy most of the channel and under normal flood tide conditions will cause the fresh water to spread out laterally. Since the west side of the channel would be blocked by the proposed Brookley Spoil Peninsula, and the north dike of the spoil site is oriented to the southeast, most of the fresh water will be directed to the southeast. At the present time most of the fresh water flow goes down the west side of Mobile Bay. More fresh water will also be directed to the southeast between Pinto Island and Little Sand Island because of the restriction in flow caused by the Brookley Peninsula. Model tests indicate an increase in the salinities of the upper bay area, especially near the channel, a decrease in the vicinity of Bon Secour Bay, and probable increases in the salinity of the lower bay west of the channel. The effect on oyster production in the lower bay cannot be accurately predicted from these model studies; however, changes in salinity are known to impact shellfish production. The Final EIS should explain the probable physical and biological consequences of these salinity alterations in greater detail.

Page 6, c. Objectives to Be Considered in Discharge Determination

The EPA guidelines state that (1) "discharge activities that significantly disrupt the chemical, physical and biological integrity of the aquatic
4. We agree that the Draft 404 Evaluation Report and DEIS inadequately described the existing shoreline in the vicinity of the Brookley Expansion Area. Further investigations of the manmade land area has revealed that about 70 acres of marsh have voluntarily established along the shoreline. Plant species mainly include Panicum sp., Phragmites communis (common reed), Hydrocotyle umbellata (pennywort), Iva frutescens (marsh-elder), Myrica cerifera (wax myrtle), Quercus nigra (water oak), Zizania aquatica (wild rice), Spartina patens (salt meadow hay), Silax nigra (black willow), Cladium jamaicense (saw grass), Baccharis halimifolia (groundsel tree), and Typha latifolia (common cattail). A large part of the wetlands area has been significantly disturbed by trash dumping and fill activities. Construction of the proposed Brookley Expansion area disposal site would eliminate this wetland area. The recommended plan provides for a marsh establishment program which will offset the wetlands loss. The 404 Evaluation Report and EIS have been expanded to discuss the loss of wetlands and mitigation.

5. Results of model studies indicate that construction of the upper bay disposal area would not be expected to significantly affect salinity gradients since the same general changes in salinity occurred with or without the Brookley Expansion area in place. Further model studies are needed to assess specific changes caused by the 55-foot deep channel and determine mechanisms for offsetting adverse impacts. See response to Comment 1.

6. As can be seen from the details in the Technical Report and EIS, the proposed plan was chosen through an extensive planning process including consideration of the EPA 404(b) Guidelines and other laws, regulations, and executive orders which require an account of economic and other factors, as well as protection of the environment. All of the topics mentioned in your comment are discussed in the EIS and 404(b) Evaluation Report. These documents recognize the significance of the project impacts and the recommended plan provides features to offset the adverse impacts.
ecosystem, etc., should be avoided." It should be recognized that the 1,710 acres of shallow water ecosystem which are eliminated by the construction of the Brookley Disposal Site represent a significant disruption of the physical and biological integrity of the aquatic ecosystem of Mobile Bay. Similarly, Section 230.4-1(a)(1) states that from a national perspective, the degradation or destruction of aquatic resources by filling operations in wetlands is considered the most severe environmental impact covered by these guidelines. You should assess the impact of either the specific or cumulative reductions. (2) "avoid discharge activities that significantly disrupt the food chain including alterations or decrease in diversity of plant and animal species." It is acknowledged in Section 4.44 that changes in salinities will be widespread and affect almost every environmental feature in the bay. Also, eliminating significant portions of shallow bay bottoms will have a detrimental effect on shrimp and fish which constitute the base of the faunal component of the trophic web.

Air quality problems already exist in Mobile County to the point of violating ambient air quality standards. It can be expected that the increase in truck and rail traffic and the secondary expansion which will take place as a result of the project will further degrade air quality unless a concerted effort is made to effect a solution. The Final EIS should detail what efforts will be made to avoid standards' violations.

If this channel deepening project is undertaken, we prefer the Gulf Disposal Plan, i.e., all material deposited in the Gulf. Although this method is not without its own adverse impacts, we believe the Gulf of Mexico has a better capacity for assimilating the huge amounts of materials involved than does Mobile Bay. This contention was expressed in our letters of October 24, 1974, and November 22, 1975, as well as by my statement at the July 31, 1979, Public Meeting. We also believe that additional modeling studies should be conducted to determine the effect of the channel deepening on water quality before the project is initiated. We are especially concerned about potential impacts to shellfish and their harvesting.

We recognize the desire on the part of State and local authorities for optimum development of port facilities, but we also feel that for every benefit to be derived there are environmental costs that must be considered. In this instance, we believe the environmental costs or damages are of sufficient magnitude to warrant offshore disposal. Similarly, maintenance material from the Theodore Industrial Channel should be taken to the Gulf after the Theodore Disposal Island is filled to capacity.

A rating of ER-2 was assigned, i.e., we have environmental reservations to the facility and additional data are required.

Sincerely yours,

John C. White
Regional Administrator
7. Construction of the project would not be expected to cause any violation in air quality standards. Sufficient regulatory controls are available to the Environmental Protection Agency and other State and local agencies to limit air pollution resulting from economic growth in the area.

8. We agree that your position for total gulf disposal is well documented. Total gulf disposal is considered by most environmental agencies to be the preferred alternative for the Mobile Harbor modifications. The EIS has been expanded to better address your position.

As you are aware, the EPA, Washington, has concurred in our selection of potential offshore disposal areas. Next detailed site specific evaluations will be conducted. The EIS has been expanded to include a discussion of the correspondence with EPA and proposed future offshore studies.

As noted in the EIS and response to your comments numbered 2 and 3, further model studies would be needed for the 55-foot deep channel.

The long-term plan for Theodore Ship Channel, presently being constructed, provides for disposal of maintenance material in the bay island disposal area. Further studies would need to be conducted to determine the location for placement of maintenance material after the island is filled to capacity. These studies are not warranted at this time.

9. Additional information has been added where appropriate and the final EIS is considered to be adequate.
District Engineer  
U.S. Army Corps of Engineers  
Post Office Box 2288  
Mobile, Alabama 36628

Dear Sir:

We have reviewed the draft environmental statement, technical report and other pertinent papers (combined) for Mobile Harbor, Mobile and Baldwin Counties, Alabama, and offer the following comments.

General Comments

The Fish and Wildlife Service views these documents as inadequate in their consideration and identification of fish and wildlife impacts. Modifications of the existing project, as well as the selected plan, are needed to reduce adverse impacts on fish and wildlife resources within the Mobile Bay area.

Dredging and spoiling associated with the construction and maintenance of the Mobile River channel have resulted in extensive fish and wildlife habitat damages in the upper bay and Mobile Delta. Page C-13, Paragraph 24 of the Technical Report states in part, "... Since inception of the Mobile Harbor project, 1,287 acres of marsh and bottomlands adjacent to Blakeley and Pinto Islands have been filled. McDuffie Island and Little Sand Island were also formed by deposition of dredged material utilizing an additional 485 acres of marsh and bottomlands." To date, no mitigation has been provided to replace these 1,772 acres of wetland losses. In addition, approximately 3.8 million cubic yards of maintenance spoil material are annually disposed over 20,000 acres of water bottoms adjacent to the bay channel. This method of disposal has altered the natural physical, chemical, and biological conditions of this valuable estuarine system. The Fish and Wildlife Service has often stressed the need for environmentally sound methods of spoil disposal. Deep gulf disposal appears to be a long-term solution to the continuous spoiling problems and is preferred over spoiling in the open bay and other wetland habitats.
1. The recommended plan does not include mitigation features for fish and wildlife losses from past modifications and maintenance of the Mobile Ship Channel since the Mobile District Corps of Engineers does not have authority to provide mitigation for the existing project. However, mitigation features have been included for future modifications to the project under the recommended plan. Mitigation for the proposed plan was developed considering in-kind replacement of losses and based upon input from the Fish and Wildlife Service and other environmental agencies at various workshops and meetings and other coordination.

Your recommendation concerning gulf disposal has been taken into consideration. As discussed in the EIS, the recommended plan provides for offshore disposal of a large portion of the new work material and all future maintenance material from the modified channel. The problems with open bay disposal of the large quantities of material would be related more to physical alteration rather than chemical or biological impacts. This has been demonstrated through studies conducted by the Army Waterways Experiment Station and the Mobile District Corps of Engineers. Present disposal of maintenance material in the bay is considered to be well within the resiliency of the estuarine system. This is discussed in more detail in the EIS, filed with the President's Council on Environmental Quality in March 1976, for maintenance of the existing Mobile Harbor Ship Channel.
A resolution by the Public Works Committee of the U.S. House of Representatives adopted June 24, 1975, authorized this study to determine if modifications of the existing project were needed. In accordance with this directive, the Fish and Wildlife Service believes that the project should be modified to provide for adequate measures to mitigate these extensive wetland losses. Recommendations to replace these wetlands will be provided in their forthcoming Fish and Wildlife Coordination Act report.

Each of the four proposed alternatives recommends deep gulf disposal as a major method for removing new work and maintenance dredge material. However, the selected plan (Blakeley Expansion and Gulf Disposal Plan I (modified)), requires that over 1,700 acres of productive shallow-water bottoms and 10 acres of tidal marshes be filled to provide additional port facilities. These marshes and water bottoms provide vital spawning and nursery habitat for a majority of the fishes that inhabit the Alabama coastal zone.

The Service believes that port expansion needs could be satisfied without destroying valuable fish and wildlife habitat. Several hundred acres of diked spoil areas are located on Blakeley, Pinto, and McDuffie Islands. These spoil sites are currently projected to be filled to capacity by the time proposed project modifications are scheduled for construction. Further studies should be conducted to determine the feasibility of using these and other areas for port expansion in lieu of filling shallow-bay waters and tidal marshes. The Theodore Industrial Park should also be utilized for additional port requirements. Furthermore, we do not believe that the filling of 1,700 acres of shallow-water bottoms and 10 acres of tidal marsh can comply with Presidential Executive Order 11990 (Protection of Wetlands) when other less damaging alternatives are feasible.

An Environmental Quality (EQ) Plan, as required by Principles and Standards, was not developed for this project. The "Channel Widening" alternative was initially identified as the EQ Plan as described on page D-31 of the Technical Report. However, this alternative was later identified as the "least environmentally damaging plan" as described on page D-69 of the report. Since an EQ Plan was not developed, trade-offs between EQ and National Economic Development (NED) objectives as outlined under Principles and Standards were not conducted in development of the selected alternative.
