

# Human Health and Ecological Risk Assessment

Main Installation  
Defense Depot Memphis Tennessee  
U.S. EPA ID # TN4210020570

Revision 1  
February 2020

# **Human Health and Ecological Risk Assessment**

Main Installation - Defense Depot Memphis, Tennessee

U.S. EPA I.D. Number TN4210020570

**Department of the Army**

**Prepared for:**

U.S. Army Corps of Engineers, Mobile District

Contract No. W91278-16-D-0061

Task Order No. 0002

**Prepared by:**

HDR

9781 S. Meridian Blvd. Suite 400

Englewood, CO 80112

**Revision 1**

**February 2020**

## Table of Contents

|                                                                         |     |
|-------------------------------------------------------------------------|-----|
| Acronyms and Abbreviations .....                                        | vi  |
| 1 Introduction .....                                                    | 1-1 |
| 1.1 Background .....                                                    | 1-1 |
| 1.2 Scope of Work.....                                                  | 1-3 |
| 1.3 Report Organization .....                                           | 1-4 |
| 2 Site Description .....                                                | 2-1 |
| 2.1 Site Contamination.....                                             | 2-1 |
| 2.2 Geology and Hydrogeology.....                                       | 2-2 |
| 3 Sample Collection, Data Refinements and Identification of COPCs ..... | 3-1 |
| 3.1 Sample Collection .....                                             | 3-1 |
| 3.1.1 Groundwater Sampling & Analytical Data .....                      | 3-1 |
| 3.1.2 Data Usability .....                                              | 3-1 |
| 3.2 Data Refinement .....                                               | 3-2 |
| 3.2.1 General Data Refinements.....                                     | 3-2 |
| 3.2.2 Data Refinements using USEPA Core of the Plume Guidance .....     | 3-3 |
| 3.3 Identification of COPCs.....                                        | 3-3 |
| 4 Exposure Assessment .....                                             | 4-1 |
| 4.1 Conceptual Site Model .....                                         | 4-1 |
| 4.2 Receptors.....                                                      | 4-1 |
| 4.2.1 Current/Future On-site Worker .....                               | 4-2 |
| 4.2.2 Future On-site Resident (Adult and Child) .....                   | 4-3 |
| 4.3 Exposure Point Concentrations.....                                  | 4-3 |
| 4.3.1 Approach for EPC Calculations.....                                | 4-3 |
| 4.4 Chemical Exposure Intake .....                                      | 4-4 |
| 4.4.1 Exposure Factors .....                                            | 4-5 |
| 4.4.2 Age-Based Adjustments for Adult and Child .....                   | 4-7 |
| 4.4.3 Mutagen Adjustments for Early Life Exposure .....                 | 4-8 |
| 5 Toxicity Assessment .....                                             | 5-1 |
| 5.1 Sources of Toxicity Values.....                                     | 5-1 |
| 5.2 Evaluation of Non-Carcinogenic Effects.....                         | 5-1 |
| 5.3 Evaluation of Carcinogenic Effects .....                            | 5-2 |
| 5.4 Health Effects of COPCs.....                                        | 5-3 |
| 6 Hazard Identification and Risk Characterization .....                 | 6-1 |
| 6.1 Non-Carcinogenic Hazard Identification.....                         | 6-1 |
| 6.2 Carcinogenic Risk Characterization .....                            | 6-1 |
| 6.3 Risk Assessment Results.....                                        | 6-2 |
| 6.3.1 Fluvial Aquifer Evaluation.....                                   | 6-2 |
| 6.3.2 IAQ Evaluation .....                                              | 6-4 |
| 6.3.3 MAQ Evaluation .....                                              | 6-5 |
| 6.3.4 Comparison of Current Risks to the 2000 MI RI Risks.....          | 6-6 |
| 6.3.5 Vapor Intrusion Evaluation .....                                  | 6-7 |
| 6.4 Risk Assessment Summary .....                                       | 6-8 |
| 6.4.1 COC Summary by Aquifer and Receptor .....                         | 6-8 |

|   |       |                                                                                     |      |
|---|-------|-------------------------------------------------------------------------------------|------|
|   | 6.4.2 | Conclusions.....                                                                    | 6-9  |
| 7 |       | Uncertainty Analysis.....                                                           | 7-1  |
|   | 7.1   | HHRA Uncertainties.....                                                             | 7-1  |
|   | 7.2   | Background Data Sensitivity Analysis.....                                           | 7-2  |
|   | 7.3   | Resident Sensitivity Analysis .....                                                 | 7-3  |
|   | 7.3.1 | Fluvial Aquifer Evaluation.....                                                     | 7-3  |
|   | 7.3.2 | IAQ Evaluation .....                                                                | 7-4  |
|   | 7.3.3 | MAQ Evaluation .....                                                                | 7-4  |
|   | 7.4   | Groundwater Core of the Plume Sensitivity Analysis.....                             | 7-5  |
|   | 7.4.1 | Groundwater EPCs Calculated using Core of the Plume Data .....                      | 7-5  |
|   | 7.4.2 | Core of the Plume - Fluvial Aquifer .....                                           | 7-6  |
|   | 7.4.3 | Core of the Plume - IAQ .....                                                       | 7-8  |
|   | 7.4.4 | Core of the Plume Risk Summary .....                                                | 7-9  |
| 8 |       | Review of 2000 Soils HHRA .....                                                     | 8-1  |
|   | 8.1   | Overview and Soils HHRA Methodology.....                                            | 8-1  |
|   | 8.1.1 | Overview .....                                                                      | 8-1  |
|   | 8.1.2 | Soils HHRA Methodology .....                                                        | 8-1  |
|   | 8.2   | Soils HHRA Issues Considered in Current Review.....                                 | 8-2  |
|   | 8.2.1 | Background Concentrations .....                                                     | 8-2  |
|   | 8.2.2 | Dioxins/Furans .....                                                                | 8-3  |
|   | 8.3   | Review of Current Conditions using 2000 MI RI Data by FU .....                      | 8-9  |
|   | 8.3.1 | FU1.....                                                                            | 8-10 |
|   | 8.3.2 | FU2.....                                                                            | 8-10 |
|   | 8.3.3 | FU3.....                                                                            | 8-10 |
|   | 8.3.4 | FU4.....                                                                            | 8-11 |
|   | 8.3.5 | FU5.....                                                                            | 8-11 |
|   | 8.3.6 | FU6.....                                                                            | 8-11 |
|   | 8.4   | Review of Removal Actions Performed After 2000 MI RI in Current<br>Conditions ..... | 8-12 |
|   | 8.4.1 | Removal Action - Building 949 in FU4.....                                           | 8-12 |
|   | 8.4.2 | Removal Action - Parcels 35 & 28 in FU3 .....                                       | 8-13 |
|   | 8.5   | Conclusions.....                                                                    | 8-13 |
| 9 |       | Review of 2000 SLERAs.....                                                          | 9-1  |
|   | 9.1   | Overview and SLERA Methodology.....                                                 | 9-1  |
|   | 9.1.1 | Overview .....                                                                      | 9-1  |
|   | 9.1.2 | SLERA Methodology .....                                                             | 9-1  |
|   | 9.2   | SLERA Issues Considered in Current Review .....                                     | 9-4  |
|   | 9.2.1 | Scientific Management Decision Points .....                                         | 9-4  |
|   | 9.2.2 | Endangered Species/Habitat.....                                                     | 9-4  |
|   | 9.2.3 | Off-site Surface Water Transport .....                                              | 9-5  |
|   | 9.3   | SLERA Conclusions and Review of Current Conditions by FU .....                      | 9-5  |
|   | 9.3.1 | FU1.....                                                                            | 9-6  |
|   | 9.3.2 | FU2.....                                                                            | 9-7  |
|   | 9.3.3 | FU3.....                                                                            | 9-8  |
|   | 9.3.4 | FU4.....                                                                            | 9-9  |
|   | 9.3.5 | FU5.....                                                                            | 9-10 |
|   | 9.3.6 | FU6.....                                                                            | 9-10 |
|   | 9.3.7 | Dioxins/Furans .....                                                                | 9-11 |

|      |                                               |      |
|------|-----------------------------------------------|------|
| 9.4  | Conclusions.....                              | 9-12 |

# 1 Introduction

HDR is pleased to submit this updated Human Health and Ecological Risk Assessment (HHERA) for potential groundwater exposures, including reviews of the HHRA for potential soil exposure and of the Screening Level Ecological Risk Assessments (SLERAs) for the Main Installation (MI) at the former Defense Depot Memphis, Tennessee (DDMT). The work was performed under Contract W91278-16-D-0061, Task Order 0002 to the United States Army Corps of Engineers (USACE), Mobile District.

The environmental restoration program at DDMT is directed by the Department of the Army (Army), Office of the Assistant Chief of Staff for Installation Management, Base Realignment and Closure (BRAC) Division. The regulatory oversight agencies are United States Environmental Protection Agency (USEPA) Region 4 and Tennessee Department of Environment and Conservation (TDEC). DDMT's USEPA Identification Number is TN4210020570.

Responses to EPA comments and EPA's conditional approval letter for this HHERA are included in [Attachment H](#).

## 1.1 Background

DDMT was added to the National Priorities List in 1992. In 1995, USEPA, TDEC, and the Army entered into a Federal Facilities Agreement (FFA; USEPA, 1995a) under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) and the Resource Conservation and Recovery Act. The FFA outlines the process for investigation and cleanup of the Depot sites under CERCLA.

DDMT consists of operable units (OUs) 1 through 4:

- OU1, Dunn Field (not included in this HHERA);
- OU2, Southwest Quadrant MI;
- OU3, Southeastern Watershed and Golf Course; and
- OU4, North-Central Area MI.

In 1995, DDMT was listed for closure under BRAC; storage and distribution of material continued until the facility closed in September 1997. Responsibility for environmental restoration at DDMT transferred from the Defense Logistics Agency to the Army in December 2010.

A Remedial Investigation (RI) was conducted at the MI to evaluate the nature and extent of contamination and the risk to human health and the environment, and to identify the need for potential remedial actions at the Depot (MI RI). The MI RI report (CH2M HILL 2000) described previous investigations performed since 1982 to evaluate whether historical operations at the Depot have affected the environment and additional investigations conducted for the MI RI from 1996 to 1998.

The MI RI was conducted for CERCLA OUs 2, 3 and 4 and to meet specific requirements for property transfer under BRAC. The MI was divided into 35 parcels, each of which comprised a unit of property that would undergo leasing and ultimately transfer for private-sector use. Additional sampling was performed in some parcels to assess environmental conditions prior to transfer. BRAC parcels and the CERCLA sites were grouped into areas of similar past activity and similar future exposure, referred to as functional units (FUs). The MI was divided into six geographic FUs, each of which was studied separately. Groundwater under the entire MI was studied as the seventh FU. The boundaries of the three OUs and the six FUs are shown on [Figure 1-1](#).

Summary descriptions of the geographic FUs from the 2000 MI RI are provided below:

- FU1, the Twenty Typical Warehouses, consists of 20 nearly identical warehouses, each 120,000 square feet (ft<sup>2</sup>) in size, built primarily to store clothing and bulk food. One building was used formerly to store hazardous materials. There is no surface water in this unit. Past storage of industrial materials and chemicals was the suspected main source of constituents of potential concern (COPCs) in this FU.
- FU2, the Southeast Golf Course/Recreational Area, has two ponds and is mostly grass covered, has a small wooded area, and has relatively small buildings. The buildings are associated with the swimming pool, golf course, tennis courts, and volleyball courts.
- FU3, the Southwest Open Area, is entirely industrialized, consisting of several buildings, open storage areas, and railroad tracks. It is covered with coarse gravel, paved roads, and railroad tracks. It was used mostly for hazardous material storage and recoupment, sandblasting, painting activities, and vehicle cleaning and maintenance. Large warehouses were used to store hazardous materials such as flammables, corrosives, and waste oil.
- FU4, the Northern and Open Areas, consists of open storage areas lined with gravel or asphalt; railroad tracks; and administrative, maintenance, and general purpose warehouse buildings. Stored items include waste materials, hazardous waste, polychlorinated biphenyl (PCB) - and non-PCB-containing transformers, petroleum products, and other materials.
- FU5, the Newer Warehouses, consists of 13 buildings surrounded by asphalt, grass, and gravel, most of which are general-purpose warehouses used to store clothes, miscellaneous equipment, medical supplies, hazardous materials, waste petroleum product drums, waste oil, and material handling equipment. Railroads used for the transport of warehoused materials are adjacent to some of the buildings.
- FU6, the Administrative and Residential Areas, consists of asphalt parking areas and a few administrative buildings; there is some grass cover in the residential area within FU6. The former base housing area, consisting of Buildings 176, 179, 181, and 184, is located south of the administrative area. Soil surrounding the four residential buildings containing elevated levels of dieldrin was removed to allow early transfer of these buildings for continued residential use. Activities at other remaining buildings include those associated with vehicle maintenance shops, a service station, vehicle storage and maintenance, heating fuel storage, a vehicle grease rack, and a gas station. This FU

also includes a former building location that was used for storing and mixing pesticides and herbicides.

The land use on the MI has not changed significantly since the 2000 MI RI and remains primarily warehousing and light industrial. Some improvements were made following transfer to the local re-use agency, Depot Redevelopment Corporation. Railroad tracks were removed, some buildings were demolished for construction of Memphis Depot Parkway and landscaping was installed around warehouses. No new buildings have been constructed since the BRAC closure was completed in 1997.

The MI RI included baseline risk assessment conducted in two parts: a risk assessment of potential harm to human health (2000 HHRA) and a screening level risk assessment of potential harm to the site ecology (plants and animals) (2000 SLERA). Both human health and ecological risk assessments were performed for each FU.

The overall conclusion from the MI RI was that facility operations had not significantly affected the environmental media at the MI: surface soil, subsurface soil, sediment, surface water, air, and groundwater. Localized areas with limited contamination were identified and either had already been cleaned up or were planned to be cleaned up.

The results of contaminant nature and extent evaluations, fate and transport analyses and risk assessments showed that residences surrounding the MI were not being exposed to site-related contamination at levels presenting potential unacceptable risk. Also, with the exception of some areas of elevated lead in surface soil, on-site workers were not being exposed to unacceptable risks within the MI.

## 1.2 Scope of Work

HDR's primary task was to update the groundwater component of the 2000 HHRA. Secondary tasks were to review the soil component of the 2000 HHRA and the overall 2000 SLERAs to evaluate the conclusions against current conditions and guidance.

The purpose of the groundwater HHRA update is to evaluate potential exposures and define risks to public health and the environment related to groundwater within the MI. The groundwater HHRA update identifies COPCs and exposure media that may pose an unacceptable risk to current and/or future human receptors in support of an ongoing Supplemental Remedial Investigation (SRI) and planned Focused Feasibility Study (FFS). Since the original risk assessment in the 2000 MI RI was completed, changes in toxicity values, exposure factors and other risk assessment guidance have occurred, which may result in a change in calculated risks. These changes between the 2000 HHRA and the groundwater HHRA update are discussed further in the [Section 6](#), Hazard Identification and Risk Characterization.

The groundwater HHRA update is focused on current risk from COPCs in groundwater because the SRI and FFS are being conducted to reevaluate the selected groundwater remedy and to revise the remedy as needed to achieve remedial action objectives (RAOs).

The groundwater HHRA update was conducted in accordance with USEPA Risk Assessment Guidance for Superfund (RAGS, USEPA 1989), USEPA Region 4 Human Health Risk Assessment Supplemental Guidance (USEPA 2018c) and other relevant risk assessment guidance as referenced in this report. It identifies the current and future land use exposure pathways for human receptors that may be exposed to contaminants in groundwater. It presents cancer risks and non-cancer hazard quotients (HQs) for potential receptors for each COPC. COPCs that contribute the most to the cumulative cancer risks and non-cancer hazard indices (HI) are identified as constituents of concern (COC) in [Section 6](#), Hazard Identification and Risk Characterization.

## 1.3 Report Organization

This report is organized into the sections described below.

**Section 1 Introduction:** Identifies the background, scope and organization of this report.

**Section 2 Site Description:** Presents the site location, history, contamination, and features.

**Section 3 Sample Collection, Data Refinements and COPC Identification:** Describes the collection and preparation of data sets and the COPCs in the groundwater HHRA update.

**Section 4 Exposure Assessment:** Presents a Conceptual Site Model (CSM) for the groundwater HHRA update that identifies the exposure pathways and potentially exposed receptors and describes how exposure intakes are calculated.

**Section 5 Toxicity Assessment:** Provides a discussion of the toxicity values and the hierarchy by which they are chosen in the groundwater HHRA update.

**Section 6 Hazard Identification and Risk Characterization:** Provides a description of the carcinogenic classes and the methods by which cancer risks and non-cancer HQs are calculated and the results of the groundwater HHRA update.

**Section 7 Uncertainty Analysis:** Describes the inherent uncertainties in the groundwater HHRA update conclusions.

**Section 8 Review of 2000 Soils HHRA:** Provides an evaluation of the previously calculated soil risk estimates in the 2000 HHRA as compared to current guidance and toxicity values and a recommendation on whether or not it should be updated.

**Section 9 Review of 2000 SLERAs:** Provides an evaluation of the previously calculated SLERAs in the 2000 MI RI as compared to current guidance and toxicity values and a recommendation on whether or not they should be updated.

**Section 10 References:** Provides complete references for the literature cited in this report.

## 2 Site Description

DDMT is located in southeastern Memphis, Tennessee, Shelby County, approximately 5 miles east of the Mississippi River and northeast of Interstate 240 ([Figure 2-1](#)). It originated as a military facility in the early 1940s and received, warehoused, and distributed supplies common to all United States military services and some civil agencies located primarily in the southeastern US, Puerto Rico, and Panama. Stocked items included food, clothing, petroleum products, construction materials, and industrial, medical, and general supplies.

The property consists of approximately 632 acres identified as the MI and Dunn Field. The MI, which is the focus of this report, is approximately 567 acres and contained open storage areas, warehouses, former military family housing, and outdoor recreational areas. Dunn Field, located across Dunn Avenue from the northwest section of the MI, is approximately 65 acres and contained mineral storage and waste disposal areas.

### 2.1 Site Contamination

Past MI activities that could have resulted in the presence of hazardous materials in environmental media at the MI include hazardous substance repackaging for storage or shipment, pesticide application, painting and sandblasting, vehicle maintenance and hazardous material handling/storage. Other historical activities in open and enclosed storage areas included storing transformers with polychlorinated biphenyls, storing and using pesticides/herbicides, and treating wood products with pentachlorophenol (PCP). These activities resulted in the presence of metals, pesticides, and other less frequently detected chemicals in surface soil, surface water and sediment, and chlorinated volatile organic compounds (CVOCs) in groundwater.

RAOs for the MI were established in the Record of Decision (MI ROD; CH2M HILL 2001). The groundwater RAOs were:

- To prevent ingestion of water contaminated with volatile organic compounds (VOCs) in excess of maximum contaminant levels (MCLs) from potential future on-site wells;
- To restore groundwater to concentrations at or less than MCLs; and
- To prevent migration horizontally and vertically offsite of groundwater contaminants in excess of MCLs.

The groundwater remedy selected in the MI ROD was enhanced bioremediation treatment (EBT) with long-term monitoring (LTM) and land use controls (LUCs). The MI ROD stated EBT would target the most contaminated areas, and that untreated parts of the groundwater plume would degrade under natural attenuation. The MI Remedial Design (CH2M HILL 2004a) used groundwater concentrations of 100 micrograms per liter ( $\mu\text{g/L}$ ) for tetrachloroethene (PCE) and trichloroethylene (TCE) to define the limit of the treatment areas (TAs).

## 2.2 Geology and Hydrogeology

The geologic units of interest at DDMT are (from youngest to oldest): loess, including surface soil; fluvial deposits; Jackson Formation/Upper Claiborne Group; and Memphis Sand. The loess consists of brown to reddish-brown, low-plasticity clayey silt to silty clay. The loess deposits are about 20 to 30 feet (ft) thick and are continuous throughout DDMT.

The fluvial (terrace) deposits at DDMT consist of two general layers. The upper layer is silty, sandy clay to clayey sand and ranges from about 0 to 30 ft thick. The lower layer is composed of interlayered sand, sandy gravel, and gravelly sand, and ranges from 30 to 100 ft thick.

The uppermost aquifer is the unconfined Fluvial aquifer, consisting of saturated sands and gravelly sands in the lower portion of the deposits. The base of the Fluvial aquifer is the uppermost clay in the Upper Claiborne; the saturated thickness ranges up to 70 ft. The groundwater in the Fluvial aquifer is not used as a drinking water source; however, the current Tennessee groundwater classification at DDMT is General Use (TDEC, 0400-40-03).

The Jackson/Upper Claiborne forms the upper confining unit for the Memphis aquifer (MAQ) on a regional basis and separates the Fluvial aquifer from the MAQ at DDMT. The Upper Claiborne Group includes the Cockfield and Cook Formations. The individual formations of the Jackson/Upper Claiborne consist of clays, silts, and sands deposited in lenses or individual beds that are not aerially extensive. The Intermediate aquifer (IAQ) is locally developed in the Upper Claiborne sands. Where clay layers are thin or absent, a hydraulic connection or 'window' is created between the Fluvial aquifer and the IAQ, and potentially, the MAQ.

The MAQ consists of thick-bedded, white to brown or gray, very fine grained to gravelly sand. The Memphis Sand ranges from 500 to 890 ft thick, and begins at a depth below ground surface (bgs) of approximately 120 to 300 ft. The MAQ is a regional deep, confined aquifer and is the primary source of water for the City of Memphis. The nearest extraction wells are within the Allen Well Field, operated by Memphis Light, Gas and Water, and located approximately 1 mile west of the MI.

The groundwater elevations for the Fluvial aquifer, IAQ and MAQ are presented in [Figures 2-2 through 2-4](#). Groundwater elevations for the wells in each of these aquifers are provided in the April 2017 LTM Summary Report (HDR 2017b) and are referenced to the North American Vertical Datum of 1988 (NAVD). The elevation ranges on the MI from the April 2017 sampling event are 243.51 to 202.44 ft NAVD in the Fluvial aquifer, 219.06 to 175.30 ft NAVD in the IAQ and 175.03 to 173.56 ft NAVD in the MAQ. Groundwater in the Fluvial aquifer flows onto the MI from all sides and migrates vertically to the IAQ through the window in the northwest MI and the sink in the south-central MI.

The MI site terrain is relatively level, with elevations ranging from 282 to 300 ft NAVD. There are only two surface water bodies on DDMT; Lake Danielson and the golf course pond. No perennial streams, flood-prone areas or wetlands occur within the Depot. The lake and pond are fed by storm water runoff and are too shallow to intercept the Fluvial aquifer.

## 3 Sample Collection, Data Refinements and Identification of COPCs

Data from groundwater samples collected by HDR from 2012 to 2017 were used to quantitatively evaluate potential human exposures to contaminants in order to assess current conditions and groundwater quality for this update to the 2000 HHRA. All data were refined for use in the risk assessment in accordance with USEPA guidance (USEPA 1992).

### 3.1 Sample Collection

#### 3.1.1 Groundwater Sampling & Analytical Data

Field activities and laboratory analyses were performed in accordance with the *Remedial Action Operations and Long Term Monitoring Quality Assurance Project Plan, Revision 0* (2011 QAPP; HDR 2011).

Groundwater samples from 161 monitoring and EBT injection wells on the MI were used to assess groundwater quality for this update. The wells used for this assessment are listed on [Table 3-1](#), and all MI monitoring wells are shown on [Figure 3-1](#). Samples collected from 17 background wells (MW-16, 19, 23, 24, 53, 55, 93, 99, 102B, 272, 274, 275, 276, 277, 278, 282 and 283) and from 8 off-site wells (MW-47, 48, 53, 66, 66A, 72, 275 and 278) were excluded from this groundwater HHRA update as they do not represent impacts from historic site activities. A discussion of the analytical data for the background locations is provided in [Section 7.2](#).

A total of 1,424 groundwater field samples were collected on the MI from 2012 to 2017; 1,159 samples were collected from 129 wells in the Fluvial aquifer, 244 samples from 29 wells in the IAQ and 21 samples from 3 wells in the MAQ. Samples from the 161 wells were collected on different frequencies (semiannual to biennial), as described in the LTM reports. The list of groundwater samples used for this assessment is shown on [Table 3-2](#).

Samples were sent to Microbac Laboratories in Marietta, Ohio for VOC analysis by Method SW8260B. Review of the quality of the analytical data was performed to ensure project data quality objectives were met. The data quality evaluation (DQE) is provided in the LTM reports. The DQE for the most recent sampling event is provided in the April 2017 LTM Summary Report (HDR 2017b).

#### 3.1.2 Data Usability

The groundwater data from the 2012 to 2017 LTM sampling events at the MI were reviewed for data quality in the annual LTM reports and it was determined the data sets met the data quality objectives (DQO) of the 2011 QAPP and are of sufficient quality to support the evaluation of remedial actions. The data were assessed for precision, accuracy, representativeness, comparability, completeness and sensitivity with minor issues as noted below.

The 2012 data set (HDR 2013) had elevated laboratory control sample (LCS) recoveries and low matrix spike (MS) and matrix spike duplicate (MSD) recoveries for the accuracy DQO; the data are qualified J or UJ and remain valid (HDR 2013). For the sensitivity DQO, the analytical reporting limits (RL) and method detection limits (MDLs) were compared to groundwater protection standards [i.e., lowest of USEPA Federal MCLs and USEPA Region 9 Preliminary Remediation Goals for Tapwater (now merged into the national USEPA Regional Screening Levels, RSLs)] and six VOCs (1,1,2,2-tetrachloroethane, 1,1,2-trichloroethane, 1,2-dichloroethane, bromodichloromethane, carbon tetrachloride, and dibromochloromethane) have MDLs greater than these standards, as noted in the 2011 QAPP, which states analytical method technology cannot achieve MDLs lower than those listed. Laboratory-established MDLs are updated annually per analytical method and matrix; the RLs remained unchanged for the duration of the project (HDR 2011).

The 2013 to 2016 data sets also have elevated LCS and low MS/MSD recoveries that result in some of the data being qualified as J or UJ; with the same VOCs with MDLs above the groundwater protection standards as identified in the 2011 QAPP, noted above (HDR 2014, 2015, 2016, 2017a).

The 2015 data set, related to compliance with the precision DQO, has one field duplicate pair at sampling location MW-92 with recovery percent differences (RPDs) above the control limit for cis-1,2-DCE, TCE, PCE and VC (HDR 2016). For the sensitivity DQO, some sample results are reported as non-detect with elevated RLs for two common laboratory contaminants, i.e., acetone and methylene chloride.

The 2016 data set, as related to the sensitivity DQO has limited sample results reported as non-detect with elevated RLs; these are for acetone and methylene chloride (HDR 2017a).

The 2017 data set, pertaining to the precision DQO, has one field duplicate pair at sampling location PMW-101 with RPDs above the control limit for PCE and methyl tert-butyl ether (HDR 2017b). Related to the sensitivity DQO, the RLs and MDLs are below the groundwater protection standards (Federal MCLs), in the LTM report (HDR 2017b) and the DDMT *Uniform Federal Policy-Quality Assurance Project Plan, Revision 1* (DDMT QAPP, HDR 2018).

## 3.2 Data Refinement

Data were reviewed in LTM and EBT performance monitoring reports in accordance with the 2011 QAPP and determined to be of appropriate quality for use in the remedial action and risk assessments. The groundwater data were further refined for use in the groundwater HHRA update.

### 3.2.1 General Data Refinements

In accordance with *USEPA Guidance for Data Useability in Risk Assessment (Part A)* (USEPA 1992) data are refined as follows:

- Chemical concentrations qualified as not detected (i.e., U-qualified data) are evaluated as non-detects. Concentrations qualified as estimated (i.e., J-qualified data) are included, while rejected (R-qualified) data are not used in risk calculations.

- The method detection limit is used to represent non-detect results; if not available, the reporting limit is used. No sample quantitation limits are identified in the data set. The non-detects are evaluated using ProUCL software and the value assigned to them is dependent upon the data distribution using the following methods. ProUCL applies the Regression on Order Statistics (ROS) methods for lognormal and gamma distributed data sets to provide a better estimate of the non-detected sample's true value based on actual detected concentrations. For normal distributions, ProUCL utilizes Kaplan-Meier estimates in lieu of the ROS methods because the ROS methods tend to yield biased and negative non-detect values for these distributions (USEPA 2015b and c).
- The results of the field duplicate samples were compared to the results of the associated parent sample and were consolidated into the data set by using the maximum result if constituents are detected in both the original and duplicate samples. The detected value is used when one result was detected and the other is reported as non-detect.
- The concentrations of m,p-xylene and o-xylene isomers are evaluated individually instead of summing the results to calculate a result for the total.

### 3.2.2 Data Refinements using USEPA Core of the Plume Guidance

Certain groundwater data are refined to meet the requirements in USEPA memorandum *Determining Groundwater Exposure Point Concentrations, Supplemental Guidance* (referred to herein as “Core of the Plume” (USEPA 2014a). The memorandum specifies which groundwater data are acceptable for lessening the variability that occurs in calculating conservative exposure point concentrations (EPCs) and includes requirements on the type of well sample (e.g., monitoring well) and data quality (e.g., low turbidity). In accordance with this guidance, data from samples collected from piezometer wells (i.e., PZ-03) are excluded from the groundwater data set, as the data may not be reproducible.

Further discussion on the evaluation of data using the Core of the Plume guidance is described in [Section 7.4](#).

## 3.3 Identification of COPCs

The COPC screening tables are presented in the format of RAGS Part D Planning Tables (USEPA 2001) in [Attachment A-1](#), RAGS Part D Planning Tables. Attachment A-1, [Table 2.1](#) presents the COPC screening of groundwater in each aquifer: Fluvial, Intermediate/Upper Claiborne and Memphis.

COPCs were determined in accordance with the criteria included in Chapter 5 of USEPA RAGS Part A (USEPA 1989) and USEPA Region 4 Human Health Risk Assessment Supplemental Guidance (2018c) as follows:

- Constituents are excluded from the COPC list if they are essential nutrients and are present at levels not likely to pose appreciable risk to human health. Chemicals that are considered to be essential nutrients include iron, calcium, chloride, magnesium, potassium and sodium (USEPA 1989). No essential nutrients were identified here as the

analytical results from 2012 – 2017 indicate primarily VOCs and some semi-volatile organic compounds (SVOCs) were detected.

- Analytical data that are not chemical-specific, e.g., total organic carbon, were excluded from the COPC list. Various acids (e.g., acetic, propionic, butyric) were excluded from the COPC list after determination that toxicity values are not available in USEPA Integrated Risk Information System (IRIS) and the acids are by-products of the sodium lactate injected for the EBT remedy.
- Tentatively identified compounds (TICs) were excluded from the COPC screening as the identity and concentration of TICs are uncertain without further analyses that were not performed.
- No constituents were eliminated based on frequency of detection (USEPA 2018c).

For the remaining constituents, the maximum detected concentrations of the constituents detected in groundwater were compared to the Federal MCLs (USEPA 2017; USEPA 2019b) and USEPA RSLs for Residential Tapwater at a target cancer risk of 1E-06 and target non-cancer HQ of 0.1 (USEPA 2019b).

If the maximum detected concentration of a constituent was less than the screening level, it was eliminated as a COPC, as it is assumed it will not contribute significantly to potential unacceptable risk (USEPA 1989). Constituents without a screening level were retained for further quantitative evaluation in the groundwater HHRA update. If the maximum detected concentration of a constituent was greater than the screening level, it too was carried through as a COPC in the groundwater HHRA update. Exceedances of screening levels do not in themselves indicate that an unacceptable exposure exists. Rather, the exceedance of a screening level indicates the need for further evaluation in the groundwater HHRA update.

The COPC screening identified 30 COPCs in the groundwater aquifers. Of these COPCs, all of the COPCs were identified in the Fluvial aquifer, 9 COPCs in the IAQ and 4 COPCs in the MAQ. The COPCs are presented in [Table 3-3](#) below as well as in Attachment A-1, RAGS Part D Planning [Table 2.Supp.1](#).

**Table 3-3      Constituents of Potential Concern**

| COPC                             | Fluvial Aquifer | IAQ | MAQ |
|----------------------------------|-----------------|-----|-----|
| 1,1,2,2-Tetrachloroethane        | X               | X   |     |
| 1,1,2-Trichloroethane            | X*              |     |     |
| 1,1-Dichloroethane               | X*              |     |     |
| 1,1-Dichloroethene               | X               |     |     |
| 1,2,3-Trichloropropane           | X               |     |     |
| 1,2,4-Trichlorobenzene           | X*              |     |     |
| 1,2,4-Trimethylbenzene           | X               |     |     |
| 1,2-Dichloroethane               | X               |     |     |
| 1,2-Dichloropropane              | X               | X*  |     |
| 1,3,5-Trimethylbenzene           | X*              |     |     |
| 1,4-Dichlorobenzene              | X*              |     |     |
| 2-Hexanone                       | X*              |     |     |
| 4-Isopropyltoluene               | X*              |     |     |
| Acetone                          | X               |     |     |
| Benzene                          | X*              |     |     |
| Bromodichloromethane             | X*              |     |     |
| Bromomethane                     | X*              |     |     |
| Carbon tetrachloride (CT)        | X               | X   | X   |
| Chloroform (CF)                  | X               | X   | X   |
| Chloromethane                    | X*              |     |     |
| cis-1,2-Dichloroethylene         | X               | X   |     |
| Ethylbenzene                     | X*              |     |     |
| Methyl Ethyl Ketone (2-butanone) | X               | X   |     |
| Methyl tert-butyl ether          | X               |     |     |
| Methylene chloride               | X               |     |     |
| PCE                              | X               | X   | X   |
| Toluene                          | X               |     |     |
| TCE                              | X               | X   | X   |
| Vinyl chloride (VC)              | X               | X   |     |
| Naphthalene*                     | X*              |     |     |

Note: COPCs marked with a \* are detected at less than five percent in the groundwater data set.

*This page intentionally left blank*

## 4 Exposure Assessment

The objective of the exposure assessment is to estimate the magnitude, frequency, duration and routes of current and reasonably anticipated future human exposure to COPCs associated with DDMT. The exposure assessment is based on the receptor scenarios for DDMT-related COPCs via site-specific routes of exposure.

The standard default exposure factors recommended by USEPA for estimating reasonable maximum exposure are used where available. Where standard default exposure factors are not available for an exposure pathway, the evaluation is conducted using similarly conservative exposure factors that are based on site-specific considerations and professional judgment to assure protectiveness.

This section presents a CSM ([Figure 4-1](#)) that identifies the exposure pathways and the potentially exposed receptors. It also describes the receptors and exposure pathways and if they will be evaluated quantitatively and qualitatively and the rationale for each chosen pathway.

### 4.1 Conceptual Site Model

The CSM is a dynamic tool for understanding DDMT conditions and potential exposure scenarios for human receptors that may be exposed to DDMT-related contamination. An exposure pathway consists of:

- A source (e.g., storage of hazardous materials) and mechanism of constituent release from source;
- A retention or transport medium (e.g., groundwater) for the constituent;
- A point of contact (e.g., drinking water) between the human receptor and the medium; and
- A route of exposure (e.g., ingestion) for the potential human receptor at the contact point.

An exposure pathway is considered complete only if all four components are present. In this groundwater HHRA update, only complete exposure pathways are evaluated quantitatively. A schematic presentation of the CSM is included as [Figure 4-1](#) and in a tabular format in Attachment A-1, RAGS Part D Planning [Table 1](#).

### 4.2 Receptors

Potential receptors are defined as human populations that are subject to contaminant exposure. Both current and future land and water use conditions are considered when determining exposure scenarios.

The property is currently used for commercial warehousing and light manufacturing in accordance with its light industrial zoning. DDMT is located in an area of mixed residential,

commercial and industrial land use. The surrounding area contains small commercial and manufacturing uses to the north and east and single-family residences to the south and west. Airways Boulevard, located on the east border of the MI, is the most heavily traveled thoroughfare in the vicinity and is developed with numerous small, commercial establishments, particularly in the area from DDMT south to the Interstate 240 interchange.

Site-wide LUCs have been implemented to prevent residential land use, daycare facilities, drilling and groundwater use, as well as to control site access, except for a portion of the eastern parcel of DDMT, which is available for unrestricted use – see [Figure 1-1](#). LUCs are being implemented through deed and lease restrictions, zoning regulations, a Notice of Land Use Restrictions (NLUR) recorded in January 2005, and annual inspections since 2005. The *Main Installation Interim Remedial Action Completion Report, Revision 1* (HDR|e2M 2010) was approved by USEPA in March 2010. The 2017 *Main Installation Annual Land Use Control Inspection Report* (HDR 2017c) was submitted to USEPA and TDEC on 8 August 2017; no deficiencies or violations of the LUCs were identified in that report.

The following potential receptors are identified: current/future on-site worker (composite of an indoor and outdoor worker) and future on-site resident adult and child. These receptors are depicted in diagram format on [Figure 4-1](#) and in tabular format in Attachment A-1, RAGS Part D Planning [Table 1](#).

#### 4.2.1 Current/Future On-site Worker

The future on-site worker is assumed to include employees that perform activities indoors and outdoors. They are involved with future non-intrusive indoor and outdoor activities, such as landscape maintenance and owner/tenant operations.

Contamination is present in the Fluvial and Intermediate/Upper Claiborne aquifers and there is potential for contamination to migrate to the deeper MAQ, which serves as a current source of drinking water. Ingestion and dermal contact with tapwater will be evaluated for a current/future worker, assuming no controls are in place to prohibit exposure to contaminated groundwater.

Exposure assumptions are based on default values representing Reasonable Maximum Exposure (RME) conditions for chronic exposures, based on methods included in EPA's Risk Assessment Guidance for Superfund (RAGS), Part B Manual (1991) and additional guidance. The National Contingency Plan (NCP) encourages protection of ground water to its greatest beneficial use; if it is suitable as a potable water source, risk assessment is to be based on residential use as the assumed most exposed receptor.

Inhalation of COPCs by workers from exposure to tapwater (e.g., from hand washing and drinking) during the work day is considered insignificant as compared to the exposure associated with longer time periods spent, for example, living in a home and the greater level of volatilization and inhalation of contaminants during a shower.

Inhalation via vapor intrusion (VI) by workers and residents is evaluated using the USEPA Vapor Intrusion Screening Level (VISL) calculator and Johnson & Ettinger (J&E) model as discussed in [Section 6.3.5](#).

A construction worker's exposure to groundwater seeping in to trenches is expected to be limited to small amounts of perched water within the clayey soils that extend to at least 20 ft bgs. The depth to water in the shallow Fluvial aquifer ranges from 55 to 100 ft bgs on the MI. Therefore, this receptor is not included in this update.

#### 4.2.2 Future On-site Resident (Adult and Child)

Redevelopment of DDMT for future residential land use is not expected, as it is continuing to be used for industrial purposes, and LUCs have been implemented to prevent building of residences and installation of wells over the majority of DDMT. However, there is potential for contamination to migrate to the MAQ. In addition, the USEPA memorandum titled *Role of the Baseline Risk Assessment in Superfund Remedy Selection Decisions* (USEPA 1991a) requires the assumption of no treatment of the water source and no institutional (e.g., restrictive ordinances) or engineering (e.g., point of entry treatment) controls in identifying routes of exposure.

Therefore, a future on-site resident was evaluated in this groundwater HHRA update. Risks potentially associated with ingestion and dermal contact of COPCs from tapwater and the inhalation of VOCs during showering were evaluated for this receptor.

### 4.3 Exposure Point Concentrations

Developing estimates of COPC concentrations at points of potential human exposure is necessary to evaluate chemical intakes by potentially exposed individuals. The concentrations of chemicals in the exposure medium at the exposure point are termed "exposure point concentrations". EPCs are determined as detailed below.

#### 4.3.1 Approach for EPC Calculations

The EPC for the groundwater HHRA update is defined as the 95 percent upper confidence limit (UCL) of the lower of the arithmetic mean or maximum observed concentration of an individual COPC, in each aquifer considered and assuming no treatment prior to exposure. Calculation of the 95% UCL is conducted in accordance with USEPA guidance (USEPA 2002; 2015b and c). The ProUCL software package, version 5.1 is used to determine the underlying statistical distributions and EPCs.

EPCs were calculated for groundwater as follows:

- Site-wide Fluvial aquifer groundwater for a worker and resident's exposure;
- Site-wide IAQ groundwater for a worker and resident's exposure; and
- Site-wide MAQ groundwater for a worker and resident's exposure.

The EPCs for each medium in the exposure assessment are presented in Attachment A-1, RAGS Part D Planning [Tables 3.1](#) through [3.3](#). [Table 3.1](#) presents the EPCs for the Fluvial aquifer, [Table 3.2](#) for the IAQ and [Table 3.3](#) for the MAQ. The supporting ProUCL data input and outputs are provided in [Attachment B](#).

## 4.4 Chemical Exposure Intake

The EPCs were used in combination with exposure factors from USEPA guidance and standard default parameters (USEPA 2011a) to estimate chemical intake via each exposure pathway for each receptor. Some default exposure factors have been updated in the 2014 USEPA Office of Solid Waste and Emergency Response (OSWER, now Office of Land and Emergency Management, OLEM) Directive 9200.1-120 (USEPA 2014b); these values were incorporated.

Chemical intake is expressed in terms of milligrams of chemical per kilogram of body weight per day (mg/kg-day), using the following general equation, which is adjusted based on the exposure pathway and medium:

$$Intake = \frac{EPC \times IR \times EF \times ED}{BW \times AT}$$

Where:

- Intake = daily intake or exposure dose (mg/kg-day)
- EPC = exposure point concentration of COPC (µg/L)
- IR = ingestion rate; the amount of contaminated medium ingested over the exposure period (liters per day [L/day])
- EF = exposure frequency; describes how often exposure occurs (days/year)
- ED = exposure duration; describes how long exposure occurs (years)
- BW = body weight; the average body weight over the exposure period (kg)
- AT = averaging time; period over which exposure is averaged (days)

Each of the intake variables in the above equation consists of a range of values taken from *RAGS, Part A through F* (USEPA 1989; USEPA 2009) and other applicable risk guidance, e.g., the *Exposure Factors Handbook* (USEPA 2011a). The exposure factors and intakes for receptor population groups for each exposure pathway are presented in Attachment A-1, RAGS Part D Planning [Table 4.1](#) and are summarized below. Attachment A-1, [Table 4.1](#) describes in more detail the exposure factors and equations for pathways related to groundwater exposure scenarios. Supplemental values for the exposure factors are presented in Attachment A-1, [Tables 4.Supp.1 to 4.Supp.3](#).

This HHRA presents the risk estimates for a resident's dermal and inhalation pathways using the USEPA Region 4 methodology, which assumes that the risk estimates for inhalation and dermal exposure from a resident showering is equivalent to exposure from the daily ingestion of 2.5 L of contaminated water per day (with supporting tables provided in [Attachment A-1](#)). The risk estimates resulting from use of the national USEPA methodology (USEPA 2018c) are presented in [Section 7.3](#), Resident Sensitivity Evaluation, as part of the uncertainties discussion (with supporting tables provided in [Attachment A-2](#)). The Core of the Plume Sensitivity analysis is presented in [Section 7.4](#), using the national methodology (with supporting tables included in [Attachment D](#)).

#### 4.4.1 Exposure Factors

The AT for cancer risk and BW are the same for all exposure pathways, as follows:

- The AT for evaluating cancer risk is equal to a lifetime of 70 years or 25,550 days (USEPA 2014a). The AT for evaluating non-cancer HQs is equal to the ED, which varies by receptor (USEPA 2014a).
- The body weight of 80 kg is the standard USEPA-recommended body weight for assessing exposure to adults; a body weight of 15 kg is used for children (0 to 6 years; USEPA 2014a).

##### 4.4.1.1 Ingestion Pathway of Exposure

- *Ingestion Rate*

The IR of groundwater via tapwater by a worker is 1.25 L/day, which is assumed to be half of an individual's daily water intake (i.e., a resident's IR; USEPA 2014a FAQs).

Residents are assumed to drink 2.5 L/day of tapwater as an adult and 0.78 L/day as a child (0 to 6 years), which are weighted averages of 90<sup>th</sup> percentile values for ingestion of drinking water (USEPA 2014a).

- *Exposure Duration and Frequency*

The worker is assumed to be exposed to contaminants in tapwater for 250 days/year for 25 years (USEPA 2014a; USEPA 2019b).

Resident adults are assumed to ingest groundwater-derived tapwater 350 days/year for 20 years (USEPA 2019b). The same EF of 350 days/year is also applied to a resident child, for 6 years (USEPA 2014a; USEPA 2019b).

##### 4.4.1.2 Dermal Contact Pathway of Exposure

The dermal contact pathway of exposure for an industrial worker and adult and child resident were evaluated using the exposure factors in [Attachments A-1, A-2 and D](#), and described below.

- *Skin Surface Area*

The skin surface area available for contact with water for a worker is 3,527 square centimeters (cm<sup>2</sup>), which is based on the weighted average of mean values for head, hands and forearms (male and female, 21+ years, USEPA 2014a).

The skin surface area available for contact with water during showering for a resident is 19,652 cm<sup>2</sup> for an adult and 6,365 cm<sup>2</sup> for a child (0 to 6 years), which are weighted average of mean values for total surface area of the whole body (USEPA 2014a). These values are greater than the skin surface area for contact with surface water, as it is assumed there will be more skin exposure to water during showering.

- *Absorbed Dose per Event in Water*

The dermally absorbed dose per event (DA-event) from water contact is calculated using default equations and values presented in *RAGS Part E* (USEPA 2004). Chemical-

specific dermal factors incorporated in the calculation include dermal permeability constant ( $K_p$ ), ratio of permeability coefficients ( $B$ ), lag time per event ( $\tau$ -event), time to reach steady state ( $t^*$ ) and fraction absorbed water ( $FA$ ). The calculations of DA-event for each aquifer and receptor scenario are presented in Attachment A-1, RAGS Part D Planning [Tables 4.Supp.3A](#) through [3C](#).

- *Exposure Duration and Frequency*

The ED and EF for each scenario is the same as those identified for the ingestion pathway above.

- *Event Duration (t-event) and Frequency*

The event frequency is assumed to be one event/day for all exposures (USEPA 2004).

The t-event is 1 hour for a worker, which assumes hand washing during breaks and meals.

The t-event for a resident showering is assumed to be 0.71 hour/event for an adult and 0.54 hour/event for a child, which are weighted averages of the 90<sup>th</sup> percentile spent bathing or showering in a day (USEPA 2014a).

#### 4.4.1.3 Inhalation Pathway of Exposure

As noted in [Section 4.2](#), potential risks related to the VI pathway have been evaluated separately using the EPA VISL calculator; see [Section 6.3.5](#).

The following refers to residential exposure during showering. As noted in the dermal pathway discussion above, the USEPA Region 4 methodology of assuming that the risk estimates for dermal/inhalation exposures are equivalent to those attributable to ingestion exposures was utilized (with supporting calculations provided in [Attachment A-1](#)). In comparison, the risk estimates using national USEPA methodology are presented in [Section 7.3](#), Resident Sensitivity Evaluation, as part of the uncertainties discussion (with supporting calculations in [Attachment A-2](#)). The exposure factors used in [Attachments A-1](#), [A-2](#) and [D](#) are described below.

- *Concentration in Air*

The Andelman model as modified by Schaum et al. as referenced in *Water Consumption and Health: Integration of Exposure Assessment, Toxicology, and Risk Assessment* (Wang 1994) is used to estimate the chemical concentration in air ( $C_a$ ) of VOCs during time spent showering and in the bathroom for a resident adult and child. In the derivation of  $C_a$ , it is assumed that the volume of the bathroom is 6 cubic meters ( $m^3$ ), the shower water flow rate is 1000 L/hour and the fraction of chemical concentration volatilized is 0.9, which are all based on upper estimates of the range of values presented in the Andelman model (Wang 1994). The calculations to model groundwater concentrations in air concentrations are presented in Attachment A-2, RAGS Part D Planning [Tables 4.Supp.4A](#) through [4C](#) for each aquifer scenario.

The total exposure time for showering is 0.71 hour for an adult and 0.54 hour for a child (USEPA 2014a). Since the Andelman model separates out exposure during showering from exposure while in the bathroom, professional judgment is used to split up the time

spent for each in the calculation of the air concentration. For adult exposure, 15 minutes (min) for showering followed by 28 min in the bathroom, for a total of 43 min (0.71 hour) is assumed. For a child, approximately 20 min bathing followed by 13 min in the bathroom, for a total of 33 min (0.54 hour) is assumed. These values are consistent with the exposure time range identified in Table 1 of the Andelman model study (Wang 1994), USEPA-recommended assumptions in Exhibit 3-2 of *RAGS Part E* (USEPA 2004) and fall within the range of estimates presented in Table 16-1 of the *Exposure Factors Handbook* (USEPA 2011a).

- *Exposure Time*

The exposure times for inhalation of groundwater-derived water vapor during showering are 0.71 hour/day for a resident adult and 0.54 hour/day for a resident child (0 to 6 years), which are weighted averages of the 90<sup>th</sup> percentile spent bathing or showering in a day (USEPA 2014a).

- *Exposure Duration and Frequency*

The EDs and EFs are the same as those identified for the ingestion pathway above.

#### 4.4.2 Age-Based Adjustments for Adult and Child

The groundwater HHRA update calculations incorporate age-adjustments for each COPC in the exposure intake term for calculating the cancer risk over the lifetime of a resident or recreator as both a child and adult. For the ingestion exposure pathway, the adjusted IR is a summation of the individual IRs weighted by the body weights and EDs of the receptor from birth to 26 years as described in the USEPA RSL equations (USEPA 2019b).

$$IR_{Adj} = \sum \frac{ED \times IR}{BW}$$

Where:

- IR-Adj = Adjusted ingestion rate (mg-year/day-kg)
- ED = Exposure duration (year)
- IR = Ingestion rate (mg/day)
- BW = Body weight (kg)

For the dermal exposure pathway, the adjusted surface area is a summation of the individual surface areas weighted by the BWs and EDs of the receptor from birth to 26 years similar to the above equation.

The age-adjustment equations are presented in Attachment A-1, RAGS Part D Planning [Table 4.1](#) and calculated in Attachment A-1, [Table 4.Supp.1](#).

The inhalation exposure pathway does not require an age-adjustment as per *RAGS Part F, Appendix A, Section 6.1* (USEPA 2009).

#### 4.4.3 Mutagen Adjustments for Early Life Exposure

USEPA has identified several carcinogens that act via a mutagenic mode of action (MMOA). To account for their early life exposures, age-dependent adjustment factors (ADAFs) have been incorporated into the intake equation. This approach is consistent with the 2005 *Guidelines for Carcinogen Risk Assessment* (USEPA 2005a) and the *Supplemental Guidance for Assessing Susceptibility from Early Life Exposure to Carcinogens* (USEPA 2005b). The intake equations are described in the USEPA RSL equations (USEPA 2019b); the equation for the ingestion exposure pathway is shown here:

$$IR_{Adj} = \sum \frac{ED \times IR}{BW} \times ADAF$$

Where:

ADAF = Age dependent adjustment factors, where  
0-<2 years applied an ADAF of 10,  
2-<6 years applied an ADAF of 3,  
6-<16 years applied an ADAF of 3, and  
16-26 years applied and ADAF of 1.

For the dermal exposure pathway, the adjusted surface area is a summation of the individual surface areas weighted by the BWs and EDs of the receptor from birth to 26 years. That surface area is then multiplied by the ADAF, similar to the above equation.

The MMOA age adjustment equations are presented in Attachment A-1, RAGS Part D Planning [Table 4.1](#) and calculated in Attachment A-1, [Table 4.Supp.2](#).

Exposure intakes for the mutagen TCE incorporate specific calculations, as the toxicity assessment for TCE requires that we address the mutagenic effects on the kidney versus the standard cancer effects on the liver and potential for developing non-Hodgkin's lymphoma. To accomplish this, the mutagenic and standard cancer equations are combined. The different toxicity values for use in the cancer and mutagen intake equations are incorporated using a toxicity value adjustment factor for cancer (CAF) and mutagens (MAF) for all exposure pathways as described in the USEPA RSL equations (USEPA 2019b).

For the mutagen VC, exposure intakes also incorporate specific calculations that are based on the USEPA RSL equations (USEPA 2019b). In the equations, early-life exposure is estimated assuming a lifetime of exposure using the adult slope factor. When evaluating both early life and adult exposures, the early life exposure is added to exposure as an adult, which can be pro-rated (ODEQ 2010).

All of the mutagen equations are presented in Attachment A-1, RAGS Part D Planning [Table 4.1](#).

## 5 Toxicity Assessment

The toxicity assessment provides a framework for characterizing the relationship between the magnitude of exposure to a COPC and the nature and likelihood of adverse health effects that may result from such exposure. For all exposure pathways, there are two approaches for deriving toxicity values. One involves the derivation of a non-cancer reference value, i.e., an oral or dermal reference dose (RfD) and inhalation reference concentration (RfC), while the other involves derivation of a predictive cancer risk estimate, i.e., an oral or dermal cancer slope factor (CSF) and inhalation unit risk (IUR). An overview of the hierarchy to apply toxicity values is described in [Section 5.1](#). The methodology used to develop a toxicity assessment as part of the groundwater HHRA update is provided in [Sections 5.2](#) and [5.3](#).

### 5.1 Sources of Toxicity Values

Pertinent toxicological information on COPCs is selected from the following sources, in descending order of hierarchy, in accordance with USEPA's OSWER Directive 9285.7-53, *Human Health Toxicity Values in Superfund Risk Assessments* (USEPA 2003a).

- Tier 1 – USEPA's IRIS (USEPA 2018a).
- Tier 2 – USEPA's Provisional Peer Reviewed Toxicity Values (PPRTVs) – The Superfund Health Risk Technical Support Center develops PPRTVs on a chemical specific basis when requested by USEPA's Superfund program (USEPA 2019a).
- Tier 3 – Other Toxicity Values – Tier 3 includes additional USEPA and non-USEPA sources of toxicity information (ATSDR 2017; Cal EPA 2016 and USEPA 2011b). Priority is given to sources of information that are the most current, transparent, publicly available and those which have been peer reviewed.

The USEPA RSL tables provide toxicity values following the above hierarchy; therefore, the RSL summary table is used as the source of toxicity values (USEPA 2019b). At the time of this groundwater HHRA update, the RSLs were last updated in May 2019.

The cancer and non-cancer toxicity values for the COPCs that are used in the risk assessment are presented in Attachment A-1, RAGS Part D Planning [Tables 5.1](#) through [6.2](#).

### 5.2 Evaluation of Non-Carcinogenic Effects

An oral RfD is calculated for the ingestion exposure pathway; typically expressed as mg/kg-day. An RfC is calculated for the inhalation pathway, expressed in terms of the concentration in the air, in units of mg/m<sup>3</sup>.

In the current absence of dermal slope factors, USEPA has devised a process that utilizes the dose-response relationship obtained from oral administration studies and makes an adjustment for absorption efficiency to represent the toxicity factor in terms of absorbed dose, using route-to-route (oral-to-dermal) extrapolations for systemic effects. This is performed using a chemical-specific oral gastrointestinal absorption factor (GIABS) that accounts for the fact that most slope

factors are expressed as the amount administered per unit time and body weight, with exposure estimates for the dermal pathway expressed as a dose absorbed in the gastrointestinal tract (USEPA 1989; USEPA 2004).

In the calculation of these toxicity values, USEPA uses values (i.e., No Observable Adverse Effect Levels and Lowest Observable Adverse Effect Levels) that express the potential non-carcinogenic effects to identify thresholds for each chemical, and derive an estimate of the exposure below which adverse health effects are not expected to occur over a lifetime.

Two types of non-cancer toxicity values are available from USEPA depending on the length of exposure being evaluated (i.e., chronic or sub-chronic). Chronic toxicity values are specifically developed to be protective for long-term exposure to a compound, and are generally used to evaluate the non-carcinogenic effects associated with exposure periods between 7 years and a lifetime. Sub-chronic toxicity values are useful for characterizing potential non-carcinogenic effects associated with shorter-term exposures. A combination of chronic and sub-chronic toxicity values are presented in the RSL summary table (USEPA 2019b), which is used as the source of toxicity values for this groundwater HHRA update.

The non-cancer toxicity values for the COPCs that are used in the risk assessment are presented in Attachment A-1, RAGS Part D Planning [Tables 5.1](#) and [5.2](#).

### 5.3 Evaluation of Carcinogenic Effects

Carcinogenic risks associated with a given level of exposure to potential carcinogens are typically extrapolated based on slope factors or unit risks. Oral slope factors are the upper 95<sup>th</sup> percent confidence limit of the slope of the dose-response curve, expressed in terms of risk per unit dose [(mg/kg-day)<sup>-1</sup>]. IURs similarly relate the risk of cancer development with the concentration of carcinogen [(mg/m<sup>3</sup>)<sup>-1</sup>].

In the absence of dermal toxicity values for cancer development, USEPA uses the oral dose-response relationship obtained from oral administration studies and adjusts for absorption efficiency with a GIABS factor to derive an absorbed dose in order to assess dermal exposure impacts for cancer, which is described in [Section 5.2](#) above (USEPA 1989; USEPA 2004).

The cancer toxicity values for the COPCs that will be used in the risk assessment are presented in Attachment A-1, RAGS Part D Planning [Tables 6.1](#) and [6.2](#).

For constituents that USEPA assessed prior to publication of the *Guidelines for Carcinogen Risk Assessment* (USEPA 2005a), USEPA considers those belonging to the following cancer weight of evidence groups to be human carcinogens (USEPA 1986):

- Group A – Known Human Carcinogen – Sufficient evidence of carcinogenicity in humans;
- Group B1 – Probable Human Carcinogen – Limited evidence of carcinogenicity in humans;

- Group B2 – Probable Human Carcinogen – Sufficient evidence of carcinogenicity in animals with inadequate or lack of evidence in humans; and
- Group C – Possible Human Carcinogen – Limited evidence of carcinogenicity in animals and inadequate or lack of evidence in humans.

For constituents that USEPA assessed after the 2005 Guidelines were published, USEPA uses a narrative approach to characterize carcinogenicity (USEPA 2005a):

- Carcinogenic to Humans
- Likely to be Carcinogenic to Humans
- Suggestive Evidence of Carcinogenic Potential
- Inadequate Information to Assess Carcinogenic Potential

As shown in Attachment A-1, RAGS Part D Planning [Tables 6.1](#) and [6.2](#), approximately half of the 30 COPCs are known carcinogens or are likely to be carcinogenic.

## 5.4 Health Effects of COPCs

The potential health effects from human health exposure to COPCs in media that are the primary contributors to the risks (see [Section 6.3](#)) are described here, as they are important for understanding the relevance of the risk estimates determined in this groundwater HHRA update. The information presented here is consistent with the basis of the toxicity values determined by USEPA IRIS and other agencies.

- TCE affects the CNS, kidney, liver, immune system, male reproductive system and developing fetus. IRIS and IARC indicate TCE is carcinogenic to humans and available human data strongly suggest the possibility of TCE-induced kidney cancer and the potential for liver cancer and malignant lymphoma in humans. TCE has similar toxicokinetics as that noted for PCE above (ATSDR 2014b).
- VC primarily affects the liver, but also the heart and blood vessels, immune system and developing fetus. IRIS indicates it is a known human carcinogen. Inhalation-based absorption of VC in humans is rapid even at low concentrations. There are no data regarding oral or dermal absorption in humans or distribution of VC in the body (ATSDR 2006).
- 1,2,3-trichloropropane affects the respiratory system with short term exposure causing eye and throat irritation, and long term exposure leading to liver and kidney damage. IRIS indicates 1,2,3-trichloropropane is likely to be carcinogenic to humans via the oral route based on the formation of multiple tumors in animals and data have not been assessed via the inhalation route. 1,2,3-trichloropropane is mobile, can stay in groundwater for a long time sinking to the bottom of the aquifer, and does not adsorb to soil. It does not bioaccumulate. Upon entering the body, it passes through the stomach within the same day (ATSDR 2011).

- CF affects the CNS, such as depression and irritability, as well the liver causing hepatitis and jaundice. IRIS has classified CF as a Group B2 probable human carcinogen. CF breaks down slowly in the air, is mobile and persists in groundwater and does not adsorb to soil. It breaks down to phosgene and hydrogen chloride, which are toxic. It does not bioaccumulate. CF quickly enters the bloodstream via the lungs and intestines and collects in body fat or remains unchanged in the air that is breathed out (ATSDR 1997; USEPA 2016a, 2018a).

## 6 Hazard Identification and Risk Characterization

The information obtained from the exposure assessment ([Section 4](#)) and toxicity assessment ([Section 5](#)) is integrated to identify the potential non-carcinogenic hazard and characterize excess lifetime cancer risk (ELCR) posed by COPCs selected for evaluation in the groundwater HHRA update. The risk associated with exposure to individual COPCs is described and then the risk associated with exposures to multiple COPCs is characterized.

### 6.1 Non-Carcinogenic Hazard Identification

Potential hazards for non-carcinogenic effects are typically estimated by calculating the HQ for each COPC, using the following general equation, which can vary by exposure pathway.

$$HQ = \frac{Intake}{Toxicity}$$

Where:

HQ = Hazard quotient (unitless)

Intake = Chronic daily intake of chemicals or exposure dose  
(mg/kg-day or mg/m<sup>3</sup>)

Toxicity = Oral reference dose (mg/kg-day), dermal reference dose  
(mg/kg-day) or inhalation reference concentration (mg/m<sup>3</sup>)

The cumulative non-cancer HI from exposure to the combination of COPCs in an environmental medium and across all media for a receptor is estimated using the following equation (USEPA 1989):

$$Hazard\ Index = \sum_i HQ_i$$

When the HI for a COPC exceeds unity (1), there may be concern for potential non-cancer effects from that COPC. The HI is an indicator that potential hazard for a specific receptor exposed to a COPC in the environment cannot be ruled out, if it is greater than 1, not that the hazard actually exists. In interpreting HI values, it is important to understand that the values are estimates, based on predictive models, and are subject to the uncertainties inherent in both the estimates of exposure and toxicity benchmarks. The approach of summing non-cancer HQs across constituents and media may overestimate the non-cancer HI because constituents may target different organs in the body and have varying non-cancer health effects.

### 6.2 Carcinogenic Risk Characterization

Potential risks for carcinogenic effects are typically estimated by calculating an ELCR as a result of exposure to site-related carcinogens. Calculation of an ELCR for an exposure pathway

involves multiplying the chronic daily intake for each chemical by its upper-bound cancer slope factor, as described by the following general equation (USEPA 1989), which can vary by exposure pathway and COPC:

$$Risk = Intake \times Toxicity$$

Where:

- Risk = Cancer risk (unitless)
- Intake = Chronic daily intake of chemicals (expressed in mg/kg-day)
- Toxicity = Oral slope factor [(mg/kg-day)<sup>-1</sup>], dermal slope factor [(mg/kg-day)<sup>-1</sup>] or IUR [(µg/m<sup>3</sup>)<sup>-1</sup>]

The cumulative cancer risk from exposure to the combination of constituents in an environmental medium and also across all media for a receptor is estimated following USEPA guidance (USEPA 1989) and the following general equation:

$$Cumulative Risk = \sum_i Risk_i$$

For known or suspected carcinogens, USEPA considers acceptable exposure levels to generally be concentration levels that represent an ELCR to an individual of between one in ten thousand (1.0E-04) and one in a million (1.0E-06). As with the non-cancer HI, cumulative cancer risk is an indicator that potential risk for a specific receptor exposed to a COPC in the environment cannot be ruled out, not that risk actually exists.

## 6.3 Risk Assessment Results

The results of the hazard identification and risk characterization are presented below, by receptor and aquifer. The risk estimates for a resident are calculated using the USEPA Region 4 methodology of assuming that the risk estimates for the combined dermal/inhalation exposures are equivalent to those attributable to ingestion exposures. The cancer risks and non-cancer HQs are presented in Attachment A-1, RAGS Part D [Tables 7.1A](#) through [7.3B](#). Attachment A-1, [Tables 7.1A](#) and [B](#) present risk estimates for exposure of workers and residents groundwater in the Fluvial aquifer, respectively. Attachment A-1, [Tables 7.2A](#) and [7.2B](#) present risk estimates for exposure of workers and residents to groundwater in the IAQ. Attachment A-1, [Tables 7.3A](#) and [7.3B](#) present risk estimates for exposure of workers and residents groundwater in the MAQ. COPCs are identified for only exposure pathways that have an ELCR greater than 1.0E-06 and a HI greater than 1, considered to be primary contributors to the risk estimates.

### 6.3.1 Fluvial Aquifer Evaluation

#### 6.3.1.1 Worker

The cumulative cancer risks and non-cancer HIs by exposure pathway for a current on-site worker's exposure to COPCs in the Fluvial aquifer are summarized in [Table 6-1](#) below. Chemical-specific cancer risks and non-cancer HQs are presented in Attachment A-1, RAGS Part D Planning [Table 7.1A](#).

The total ELCR for a worker's exposure to COPCs in groundwater via tapwater from all pathways is 2.4E-04. The ELCR for groundwater ingestion exposure is 2.3E-04, with primary contributors of 1,2,3-trichloropropane at 1.9E-04, CF at 2.1E-05 and VC at 1.3E-05. The ELCR for groundwater dermal exposure is 1.1E-05, with the primary contributor being 1,2,3-trichloropropane at 9.2E-06.

The total non-cancer HI is 1.3E+00. The HI for groundwater ingestion is 1.2E+00 and the primary contributors are various VOCs with HQs less than 1. The HI for groundwater dermal exposure is below 1. See [Table 6-1](#).

**Table 6-1 Worker's Exposure to Fluvial Aquifer Groundwater**

| Exposure Route | Cumulative Cancer Risk | Primary COPCs                                                                                                           | Hazard Index | Primary COPCs                                                                                       |
|----------------|------------------------|-------------------------------------------------------------------------------------------------------------------------|--------------|-----------------------------------------------------------------------------------------------------|
|                | <i>Lifetime</i>        |                                                                                                                         |              |                                                                                                     |
| Ingestion      | 2.3E-04                | 1,2,3-trichloropropane (1.9E-04), CF (2.1E-05), VC (1.3E-05), TCE (2.4E-06), methylene chloride (1.4E-06), CT (1.4E-06) | 1.2E+00      | Methylene chloride (0.32), TCE (0.29), CF (0.19), 1,2,4-trimethylbenzene (0.15), cis-1,2-DCE (0.14) |
| Dermal         | 1.1E-05                | 1,2,3-Trichloropropane (9.2E-06)                                                                                        | 1.3E-01      | --                                                                                                  |
| <b>Total</b>   | 2.4E-04                |                                                                                                                         | 1.3E+00      |                                                                                                     |

### 6.3.1.2 Resident

The cumulative cancer risks and non-cancer HIs by exposure pathway for a future on-site resident adult and child's exposure to COPCs in the Fluvial aquifer are summarized in [Table 6-2](#) below. Chemical-specific cancer risks and non-cancer HQs are presented in Attachment A-1, RAGS Part D Planning [Table 7.1B](#).

**Table 6-2 Resident's Exposure to Fluvial Aquifer Groundwater**

| Exposure Route      | Cumulative Cancer Risk | Primary COPCs                                                                                                           | Hazard Index |              | Primary COPCs                                                                                           |
|---------------------|------------------------|-------------------------------------------------------------------------------------------------------------------------|--------------|--------------|---------------------------------------------------------------------------------------------------------|
|                     | <i>Lifetime</i>        |                                                                                                                         | <i>Adult</i> | <i>Child</i> |                                                                                                         |
| Ingestion           | 3.1E-03                | 1,2,3-trichloropropane (2.8E-03), VC (2.2E-04), CF (8.4E-05), methylene chloride (2.0E-05), TCE (1.5E-05), CT (5.5E-06) | 3.3E+00      | 5.6E+00      | For child, methylene chloride (1.5), TCE (1.4) - others are less than 1. For adult, all are less than 1 |
| Dermal / Inhalation | 6.3E-03                | See above                                                                                                               | 6.7E+00      | 1.1E+01      | See above                                                                                               |
| <b>Total</b>        | 9.4E-03                |                                                                                                                         | 1.0E+01      | 1.7E+01      |                                                                                                         |

The total ELCR for a resident's exposure to COPCs in groundwater via tapwater from all pathways is 9.4E-03. The primary contributors are 1,2,3-trichloropropane at 2.8E-03 and VC at 2.2E-04.

The total non-cancer HI is 1.0E+01 for an adult and 1.7E+01 for a child. The primary contributors are methylene chloride and TCE. See [Table 6-2](#).

## 6.3.2 IAQ Evaluation

### 6.3.2.1 Worker

The cumulative cancer risks and non-cancer HIs by exposure pathway for a current on-site worker's exposure to COPCs in the IAQ are summarized in [Table 6-3](#) below. Chemical-specific cancer risks and non-cancer HQs are presented in Attachment A-1, RAGS Part D Planning [Table 7.2A](#).

The total ELCR for a worker's exposure to COPCs in groundwater via tapwater from all pathways is 4.0E-06. The ELCR for groundwater ingestion exposure is 3.8E-06 with primary contributors of TCE at 1.6E-06 and VC at 1.5E-06.

The total non-cancer HI is less than 1 for all pathways. See [Table 6-3](#).

**Table 6-3 Worker's Exposure to IAQ Groundwater**

| Exposure Route | Cumulative Cancer Risk | Primary COPCs               | Hazard Index | Primary COPCs |
|----------------|------------------------|-----------------------------|--------------|---------------|
|                | <i>Lifetime</i>        |                             |              |               |
| Ingestion      | 3.8E-06                | TCE (1.6E-06), VC (1.5E-06) | 2.6E-01      | TCE (1.9E-01) |
| Dermal         | 2.3E-07                | --                          | 2.4E-02      | --            |
| <b>Total</b>   | 4.0E-06                |                             | 2.8E-01      |               |

### 6.3.2.2 Resident

The cumulative cancer risks and non-cancer HIs by exposure pathway for a future on-site resident adult and child's exposure to COPCs in the IAQ are summarized in [Table 6-4](#) below. Chemical-specific cancer risks and non-cancer HQs are presented in Attachment A-1, RAGS Part D Planning [Table 7.2B](#).

The total ELCR for a resident's exposure to COPCs in groundwater via tapwater from all pathways is 1.2E-04. The primary contributors are VC and TCE.

The total non-cancer HI is 2.2E+00 for an adult and 3.6E+00 for a child. The primary contributors are TCE and PCE. See [Table 6-4](#).

**Table 6-4 Resident's Exposure to IAQ Groundwater**

| Exposure Route      | Cumulative Cancer Risk | Primary COPCs               | Hazard Index |              | Primary COPCs                                                            |
|---------------------|------------------------|-----------------------------|--------------|--------------|--------------------------------------------------------------------------|
|                     | <i>Lifetime</i>        |                             | <i>Adult</i> | <i>Child</i> |                                                                          |
| Ingestion           | 3.9E-05                | VC (2.6E-05), TCE (1.0E-05) | 7.2E-01      | 1.2E+00      | TCE (adult 5.4E-01, child 9.1 E-01), PCE (adult 1.0E-01, child 1.7 E-01) |
| Dermal / Inhalation | 7.8E-05                | See above                   | 1.4E+00      | 2.4E+00      | See above                                                                |
| <b>Total</b>        | 1.2E-04                |                             | 2.2E+00      | 3.6E+00      |                                                                          |

### 6.3.3 MAQ Evaluation

#### 6.3.3.1 Worker

The cumulative cancer risks and non-cancer HIs by exposure pathway for a current on-site worker's exposure to COPCs in the MAQ are summarized in [Table 6-5](#) below. Chemical-specific cancer risks and non-cancer HQs are presented in Attachment A-1, RAGS Part D Planning [Table 7.3A](#).

The total ELCR for a worker's exposure to COPCs in groundwater via tapwater from all pathways is 6.4E-07. The total non-cancer HI is less than 1 for all pathways. See [Table 6-5](#).

**Table 6-5 Worker's Exposure to MAQ Groundwater**

| Exposure Route | Cumulative Cancer Risk | Hazard Index |
|----------------|------------------------|--------------|
|                | <i>Lifetime</i>        |              |
| Ingestion      | 5.9E-07                | 5.2E-02      |
| Dermal         | 5.3E-08                | 4.8E-03      |
| <b>Total</b>   | 6.4E-07                | 5.7E-02      |

#### 6.3.3.2 Resident

The cumulative cancer risks and non-cancer HIs by exposure pathway for a future on-site resident adult and child's exposure to COPCs in the MAQ are summarized in [Table 6-6](#) below. Chemical-specific cancer risks and non-cancer HQs are presented in Attachment A-1, RAGS Part D Planning [Table 7.3B](#).

The total ELCR for a resident's exposure to COPCs in groundwater via tapwater from all pathways is 9.5E-06. The primary contributor is TCE.

The total non-cancer HI is less than 1 for adult and child; the primary contributor is TCE. See [Table 6-6](#).

**Table 6-6 Resident's Exposure to MAQ Groundwater**

| Exposure Route      | Cumulative Cancer Risk | Primary COPCs | Hazard Index |              | Primary COPCs                      |
|---------------------|------------------------|---------------|--------------|--------------|------------------------------------|
|                     | <i>Lifetime</i>        |               | <i>Adult</i> | <i>Child</i> |                                    |
| Ingestion           | 3.2E-06                | TCE (2.2E-06) | 1.5E-01      | 2.4E-01      | TCE (adult 1.2E-01, child 2.0E-01) |
| Dermal / Inhalation | 6.3E-06                | See above     | 2.9E-01      | 4.8E-01      | See above                          |
| <b>Total</b>        | 9.5E-06                |               | 4.4E-01      | 7.2E-01      |                                    |

### 6.3.4 Comparison of Current Risks to the 2000 MI RI Risks

The groundwater component of the 2000 HHRA follows the general risk methodology described above and uses the same primary USEPA guidance as this groundwater HHRA update. However, USEPA has published additional risk assessment guidance and updated toxicity data since the 2000 HHRA was completed. These guidance documents include changes to EPA's risk assessment methodology as it relates to exposure factors, evaluation of inhalation risks, the effects of chemicals now being identified as having a MMOA, and in the calculation of groundwater EPCs.

Taken alone, without considering potential changes in COPC concentrations or other revisions to how risk is calculated, the changes can result in either an increase or decrease in the calculated risk for the COPCs; this groundwater HHRA update was performed to re-evaluate the risks to COPCs in the groundwater to help determine whether or not the remedy remains protective of the potential risks to receptors at DDMT.

It is important to note that given the different methodologies for risk calculations since 2000, it is not a straightforward comparison between the 2000 and current risk estimates, as indicated here:

- The 2000 HHRA utilized the average of the concentrations in each data set (as opposed to calculating the 95 percent UCLs that are upper estimates of the true population average) and this led to slightly lower EPCs when compared to the EPCs calculated in this groundwater HHRA update. Refer to [Table 34-4](#) in the 2000 HHRA, included in Attachment E of this groundwater HHRA update, compared to the current EPCs in Attachment A-1, [Tables 3.1](#) to [3.3](#).
- The 2000 HHRA had a larger analyte list that included inorganics. In comparison, this groundwater HHRA update evaluated VOCs and some SVOCs, as samples have been analyzed for these methods for the past 5 years. The groundwater contaminants requiring remediation in the ROD were limited to VOCs.
- The 2000 HHRA divided the groundwater data into Plumes "A", "B" and "C", which represent potential plumes in the southwest corner, southeast corner and northwest

corner, respectively. In comparison, this groundwater HHRA update evaluated groundwater by aquifer and depth, based on current understanding of where contamination exists and using the 2014 USEPA *Memorandum on Determining Groundwater Exposure Point Concentrations*. Refer to Attachment E, [page 34-1](#) and [Table 34-1](#).

- The 2000 HHRA applied inhalation toxicity values that were based on IR and body weight, which is different than the current inhalation dosimetry methodology – see Attachment E, [Table 34-5](#) compared to Attachment A-1, [Tables 5s](#) and [6s](#). Also, some of the exposure factors for each receptor scenario are different. See Attachment E, [Table 7-4c](#) compared to Attachment A-1, [Table 4-1](#).

The results of the 2000 HHRA indicated ELCRs for the three plumes with a range of 5E-06 to 8E-06 for industrial workers, a range of 2E-05 to 3E-05 for resident adults and a range of 8E-06 to 1E-05 for resident children (CH2M HILL 2000). The HIs for each receptor and plume were less than 1.

In comparison, the risk estimates calculated in this HHRA, by aquifer, using current guidance and methodology vary in being lower, higher or the same than those of the 2000 HHRA, depending on the exposure scenario and other factors.

### 6.3.5 Vapor Intrusion Evaluation

To calculate whether a VI exposure pathway is complete and to determine VI risks and hazards, the Department of Defense (DOD) *Vapor Intrusion Handbook* (DOD 2009) was used in concert with USEPA's VISL Calculator (version 3.5.1 using May 2016 RSLs; USEPA 2016c) and the J&E model (USEPA 2003b) to evaluate VI at DDMT, separately from the groundwater HHRA update calculations.

The complete VI screening level assessment is provided in [Attachment C](#). The attachment includes a VI map for the MI showing the locations of the CVOC plumes, concentrations at individual wells, groundwater elevation contours in the Fluvial aquifer and location of existing buildings.

The October 2016 groundwater analytical results were reviewed and wells DR2-1, MW-100B and PMW21-04 were selected for the VI evaluation, as they had the highest concentrations of the primary COPCs (CF, CT, PCE, TCE and VC) among the wells sampled and they are located adjacent to occupied buildings. These wells are screened in the Fluvial aquifer.

Results of the VI evaluation for a commercial scenario indicate:

- Constituents present in groundwater are sufficiently volatile and toxic to pose a potential human health risk from VI to indoor air of current and future buildings;
- Recent analytical results for COPCs in groundwater exceed commercial screening levels estimated using the VISL calculator beneath occupied buildings indicating a potential human health risk from VI; and

- The potential human health risk from COPCs in groundwater within occupied structures at DDMT is greater than  $1.0\text{E-}06$  for cancer and greater than one for non-cancer using the VISL calculator. Cancer and non-cancer risk calculated using the J&E model are almost an order of magnitude lower, but is still greater than  $1.0\text{E-}06$  for cancer.

Large portions of DDMT are paved or developed with overlying structures. This can prevent vertical migration of VOCs through the subsurface to the atmosphere. However, it may also allow for greater horizontal migration in the subsurface. A work plan has been prepared for soil gas sampling to better estimate human health risk via this pathway of potential exposure. Sampling will be conducted in 2018.

## 6.4 Risk Assessment Summary

This groundwater HHRA update was prepared to evaluate potential baseline health risks for current and future receptor exposure to COPCs in the Fluvial aquifer, IAQ and MAQ. The COPC screening of the groundwater HHRA update identified 30 COPCs from sampling events conducted from 2012 to 2017. The potential exposure scenarios considered in this groundwater HHRA update include drinking water and incidental ingestion, dermal contact and inhalation, as shown in the CSM, [Figure 4-1](#).

The evaluation of potential cancer risks and non-cancer hazards to current/future receptors on-site from exposure to COPCs in groundwater indicates that there are several COPCs, now identified as COCs whose concentrations in groundwater are the primary contributors to the hazard and risk estimates, and exposure to these COCs may result in potential adverse health effects.

### 6.4.1 COC Summary by Aquifer and Receptor

The evaluation of potential cancer risks and non-cancer hazards to on-site current/future workers indicates that 1,2,3-trichloropropane, CF, VC, TCE, methylene chloride and CT are COCs in the Fluvial aquifer. For the IAQ, TCE and VC are COCs. No COCs are identified in the MAQ. CT, CF, PCE, TCE and VC volatilizing into buildings are also of potential concern to workers.

The evaluation of potential cancer risks and non-cancer hazards to future on-site residents indicates that 1,2,3-trichloropropane, VC, CF, methylene chloride, TCE and CT are COCs in the Fluvial aquifer. For the IAQ, VC and TCE are COCs. TCE is the only COC in the MAQ.

The constituent 1,2,3-trichloropropane is an artifact of the EBT remedy and was detected in only eight wells within the TTA-2 TA, with a detected range of 0.694 to 83.3  $\mu\text{g/L}$  between 2012 and 2017. In April 2017, sampling indicated that 1,2,3-trichloropropane was detected in only four wells with a range of 0.694 to 15.9  $\mu\text{g/L}$ . The constituent 1,2,3-trichloropropane had not been detected prior to the start of enhanced bioremediation treatment and has only been detected in one area (TTA-2) that was impacted primarily by PCE, TCE and CT. Detection likely results from it being a by-product of the bioremediation process; in any case, its presence is limited and the concentration has decreased over time. TCP will continue to be analyzed during site

monitoring, with concentrations and trend analysis to be reported and the need for any remedial action evaluated.

## 6.4.2 Conclusions

The results of this groundwater HHRA update indicate that there is potential for receptors to experience adverse cancer or non-cancer health effects from exposure to the contaminated groundwater.

The *Fourth Five-Year Review* (HDR 2017d) technical assessment states that the MI EBT remedy reduced CVOC concentrations in the TAs, but not to levels below MCLs, and natural attenuation outside the TAs has been less than projected in the MI ROD.

In addition, understanding of site hydrogeology and contaminant extent on the MI has changed based on data collected from wells installed since the *Third Five-Year Review* (HDR 2012). The 2016 MI LTM Report (HDR 2017a) indicated that the areal extent of the remedial action will need to be expanded to meet the RAO for concentrations below the MCLs in the MI.

The existing land use restrictions at the MI are:

- No residential land use or other child-occupied facilities, including daycare on the MI; and
- No production/consumptive use of groundwater or drilling groundwater wells (does not apply to wells installed as part of the CERCLA action) on the MI.

As long as these restrictions are maintained, the exposure pathways to the contaminated groundwater are not complete, with the possible exception of vapor intrusion. A work plan has been prepared for soil gas sampling to better estimate human health risk via vapor intrusion. Sampling will be conducted in 2018.

## 7 Uncertainty Analysis

This section includes a discussion on the inherent uncertainties in this groundwater HHRA update, including methods, site-specific analytical data, inputs based on risk guidance and toxicity factors, and conclusions. The section also presents additional sensitivity analyses.

### 7.1 HHRA Uncertainties

There is uncertainty inherent in the methods, inputs and conclusions of any HHRA. This level of uncertainty results from the fact that almost every step in the risk assessment process involves assumptions and unknowns, contributing to the total uncertainty in the final conclusions. These include, but are not limited to:

- Knowledge of the site, including its geology, hydrology and habitat and past and current land use;
- Environmental parameters, chemistry and sampling analysis which can under- or overestimate exposure concentrations;
- Assumptions in the derivation of screening benchmarks that are used to identify COPCs;
- The exposure factors used for quantifying exposure are conservative and reflect upper-bound assumptions; which can under- or overestimate the resulting hazard and risk values;
- Maximum concentrations applied as a measure of exposure for each medium and receptor in the initial COPC screening; a conservative assumption intentionally used to focus the HHRA on those pathways and receptors potentially at greatest risk. This likely overestimates the number of COPCs identified;
- Bioavailability of 100 percent is assumed for uptake by humans. This assumption is known to be invalid for most chemical substances under varying environmental conditions and likely overestimates risks and HQs; and
- Summing non-cancer HQs across constituents and media may overestimate the non-cancer HI, as constituents may target different organs in the body and have varying non-cancer health effects.

Uncertainties specific to this groundwater HHRA update include:

- This groundwater HHRA update was performed as “baseline” that, in accordance with applicable guidance, includes consumption of drinking water with no controls. However, no one is currently using groundwater as a potable source, as LUCs have been implemented to prevent building of residences and installation of wells over the majority of the DDMT.
- Off-site groundwater data were not used in the groundwater HHRA update. It has been determined that there are potential off-site sources impacting DDMT groundwater quality, based on CVOCs being detected in off-site wells upgradient of the MI and Dunn

Field. The complexity involved in determining the contribution of these potential sources to detected levels of contamination versus that from historic activity at DDMT adds to the uncertainty inherent in the groundwater HHRA update.

## 7.2 Background Data Sensitivity Analysis

There were 24 field samples and two field duplicate samples collected between 2012 to 2017 in the Fluvial aquifer from background wells MW-16, 19, 23, 24, 53, 55, 93, 99, 102B, 272, 274, 275, 276, 277, 278, 282 and 283; the data associated with these samples were excluded from the groundwater HHRA update risk calculations. Of the 67 analytes (USEPA Target Compound List VOCs), only 13 are detected. The range of concentrations for those constituents identified as the primary CVOs in the Fluvial aquifer are generally lower compared to DDMT-related concentrations: PCE detected concentrations range from 0.4 to 2.6 µg/L; TCE concentrations from 0.34 to 1.02 µg/L; VC was not detected in any of these wells; CF concentrations range from 0.14 to 0.45 µg/L; and CT was not detected in any of these wells.

The maximum detected concentrations of these background samples are compared to the Federal MCLs (USEPA 2017, 2019b) and USEPA RSLs for Residential Tapwater at a target cancer risk of 1E-06 and target non-cancer HQ of 0.1 (USEPA 2019b). Three of the constituents are present in the Fluvial aquifer at concentrations greater than the USEPA Tapwater RSL, including 1,2-dichloroethane, CF and TCE. None of the constituents are greater than the Federal MCLs. The background maximum concentrations are less than the DDMT-related fluvial maximum concentrations, except for 1-chlorohexane and dichlorodifluoromethane. See [Table 7-1](#) below.

**Table 7-1 Comparison of Background Data to Screening Levels and DDMT-Related Data**

| Chemical                 | Background Fluvial Maximum (µg/L) | DDMT Fluvial aquifer Maximum (µg/L) | USEPA Tapwater RSL (µg/L) | Federal MCL (µg/L) |
|--------------------------|-----------------------------------|-------------------------------------|---------------------------|--------------------|
| 1,2-Dichloroethane       | <b>0.737</b>                      | 14.7                                | 0.17                      | 5                  |
| 1-Chlorohexane           | 0.131                             | ND                                  | Not available             | Not available      |

| PCE                      | 2.59                              | 300                                 | 4.1                       | 5                  |
| Toluene                  | 0.446                             | 149                                 | 110                       | 1000               |
| TCE                      | <b>1.02</b>                       | 286                                 | 0.28                      | 5                  |

**Note:** Concentrations greater than the USEPA Tapwater RSL are in **bold type**.

## 7.3 Resident Sensitivity Analysis

In contrast to the methodology used in [Section 6.3](#), the risk estimates for a resident are calculated here using the national USEPA methodology for the dermal water and shower inhalation pathways. The results of the hazard identification and risk characterization are presented below, by receptor and aquifer, and compared to the risk estimates in [Section 6.3](#). The cancer risks and non-cancer HQs are presented in Attachment A-2, RAGS Part D [Tables 7.4](#) through [7.6](#). Attachment A-2, [Table 7.4](#) presents risk estimates for exposure of residents to groundwater in the Fluvial aquifer. Attachment A-2, [Table 7.5](#) presents risk estimates for exposure of residents to groundwater in the IAQ. Attachment A-2, [Table 7.6](#) presents risk estimates for exposure of residents to groundwater in the MAQ. COPCs are identified for only exposure pathways that have an ELCR greater than 1.0E-06 and a HI greater than one, considered to be primary contributors to the risk estimates.

### 7.3.1 Fluvial Aquifer Evaluation

In comparison to the results presented in [Section 6.3.1](#), the ELCR is slightly lower, but within the same order of magnitude, while the HI values vary. Because the results of the dermal and inhalation pathway calculations are included here, other contributors to the risk estimates are identified, such as 1,2,4-trimethylbenzene, 1,1,2,2-tetrachloroethane, 1,2-dichloroethane and 1,2-dichloropropane. The cumulative cancer risks and non-cancer HIs by exposure pathway for a future on-site resident adult and child's exposure to COPCs in the Fluvial aquifer are summarized in [Table 7-2](#) below. Chemical-specific cancer risks and non-cancer HQs are presented in Attachment A-2, RAGS Part D Planning [Table 7.4](#).

**Table 7-2 Sensitivity Analysis: Resident's Exposure to Fluvial Aquifer Groundwater**

| Exposure Route | Cumulative Cancer Risk | Primary COPCs                                                                                                           | Hazard Index |         | Primary COPCs                                                                                      |
|----------------|------------------------|-------------------------------------------------------------------------------------------------------------------------|--------------|---------|----------------------------------------------------------------------------------------------------|
|                | Lifetime               |                                                                                                                         | Adult        | Child   |                                                                                                    |
| Ingestion      | 3.1E-03                | 1,2,3-trichloropropane (2.8E-03), VC (2.2E-04), CF (8.4E-05), methylene chloride (2.0E-05), TCE (1.5E-05), CT (5.5E-06) | 3.3E+00      | 5.6E+00 | For child, methylene chloride (1.5), TCE (1.4); others are less than 1. For adult, all less than 1 |
| Dermal         | 2.7E-04                | 1,2,3-trichloropropane (2.4E-04), VC (1.5E-05), CF (6.5E-06), TCE (2.0E-06), CT (1.3E-06)                               | 8.2E-01      | 1.2E+00 | For child, all less than 1                                                                         |

| Exposure Route | Cumulative Cancer Risk | Primary COPCs                                                                                                                                                                                           | Hazard Index |         | Primary COPCs                                                                                                                                                                                                                                                                                                                    |
|----------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | Lifetime               |                                                                                                                                                                                                         | Adult        | Child   |                                                                                                                                                                                                                                                                                                                                  |
| Inhalation     | 7.5E-04                | CF (7.1E-04), TCE (2.7E-05), CT (5.3E-06), VC (4.3E-06), 1,1,2,2-tetrachloroethane (2.4E-06), bromodichloromethane (2.1E-06), 1,2-dichloroethane (2.0E-06), methylene chloride (1.6E-06), PCE (1.2E-06) | 9.6E+00      | 8.1E+00 | TCE (adult 3.3E+00, child 2.8E+00), 1,2,3-trichloropropane (adult 2.6E+00, child 2.2E+00), 1,2,4-trimethylbenzene (adult 1.2E+00, child 9.8E-01), CF (adult 8.7E-01, child 7.4E-01), 1,1,2-trichloroethane (adult 7.1E-01, child 6.0E-01), PCE (adult 3.2E-01, child 2.7E-01), methylene chloride (adult 1.4E-01, child 1.2E-01) |
| <b>Total</b>   | 4.2E-03                |                                                                                                                                                                                                         | 1.4E+01      | 1.5E+01 |                                                                                                                                                                                                                                                                                                                                  |

### 7.3.2 IAQ Evaluation

In comparison to the results presented in [Section 6.3.2](#), the ELCR is lower and the HI values are higher or the same. Because the results of the dermal and inhalation pathway calculations are included here, other contributors to the risk estimates are identified, such as CF, 1,1,2,2-tetrachloroethane and PCE. The cumulative cancer risks and non-cancer HIs by exposure pathway for a future on-site resident adult and child's exposure to COPCs in the IAQ are summarized in [Table 7-3](#) below. Chemical-specific cancer risks and non-cancer HQs are presented in Attachment A-2, RAGS Part D Planning [Table 7.5](#).

**Table 7-3 Sensitivity Analysis: Resident's Exposure to IAQ Groundwater**

| Exposure Route | Cumulative Cancer Risk | Primary COPCs                                                    | Hazard Index |         | Primary COPCs                                                          |
|----------------|------------------------|------------------------------------------------------------------|--------------|---------|------------------------------------------------------------------------|
|                | Lifetime               |                                                                  | Adult        | Child   |                                                                        |
| Ingestion      | 3.9E-05                | VC (2.6E-05), TCE (1.0E-05)                                      | 7.2E-01      | 1.2E+00 | TCE (adult 5.4E-01, child 9.1E-01), PCE (adult 1.0E-01, child 1.7E-01) |
| Dermal         | 3.7E-06                | VC (1.7E-06), TCE (1.3E-06)                                      | 1.6E-01      | 2.4E-01 | TCE (adult 8.7E-02, child 1.3E-01)                                     |
| Inhalation     | 3.0E-05                | TCE (1.8E-05), CF (8.3E-06), 1,1,2,2-tetrachloroethane (2.1E-06) | 2.5E+00      | 2.1E+00 | TCE (adult 2.2E+00, child 1.9E+00), PCE (adult 2.5E-01, child 2.2E-01) |
| <b>Total</b>   | 7.3E-05                |                                                                  | 3.4E+00      | 3.6E+00 |                                                                        |

### 7.3.3 MAQ Evaluation

In comparison to the results presented in [Section 6.3.3](#), the ELCR is slightly lower and HI values are slightly higher. Because the dermal and inhalation pathway calculated risks are included here, other contributors to the risk estimates are identified, such as CT and CF. The cumulative cancer risks and non-cancer HIs by exposure pathway for a future on-site resident adult and

child's exposure to COPCs in the MAQ are summarized in [Table 7-4](#) below. Chemical-specific cancer risks and non-cancer HQs are presented in Attachment A-2, RAGS Part D Planning [Table 7.6](#).

**Table 7-4 Sensitivity Analysis: Resident's Exposure to MAQ Groundwater**

| Exposure Route | Cumulative Cancer Risk | Primary COPCs | Hazard Index |              | Primary COPCs                      |
|----------------|------------------------|---------------|--------------|--------------|------------------------------------|
|                | <i>Lifetime</i>        |               | <i>Adult</i> | <i>Child</i> |                                    |
| Ingestion      | 3.2E-06                | TCE (2.2E-06) | 1.5E-01      | 2.4E-01      | TCE (adult 1.2E-01, child 2.0E-01) |
| Dermal         | 5.3E-07                | --            | 3.2E-02      | 4.7E-02      | --                                 |
| Inhalation     | 5.7E-06                | TCE (4.0E-06) | 5.4E-01      | 4.6E-01      | TCE (adult 4.9E-01, child 4.2E-01) |
| <b>Total</b>   | 9.4E-06                |               | 7.2E-01      | 7.5E-01      |                                    |

## 7.4 Groundwater Core of the Plume Sensitivity Analysis

The USEPA "Core of the Plume" guidance (USEPA 2014a) provides a recommended approach to improve the quality and consistency in calculating groundwater EPCs. The approach involves evaluating data from the "core/center of the plume," which is defined as the three-dimensional core/center zone of highest concentrations of each constituent within a delineated groundwater plume.

This groundwater HHRA update includes an evaluation of groundwater scenarios in the primary risk calculations using all of the groundwater data in each aquifer for the COPCs. A sensitivity analysis was also performed that calculates more conservative groundwater EPCs for the Core of the Plume subset of data. That data set includes data for the five wells with the highest maximum detected concentrations for the COPCs identified in [Section 3.3](#). The supporting tables for the evaluation are presented in [Attachment D](#). The Core of the Plume sensitivity analysis evaluates the Fluvial aquifer and IAQ; it does not include the MAQ, as there are limited data available for this aquifer and the results of a Core of Plume analysis would be the same as the initial results. The Core of the Plume sensitivity analysis includes risk estimates based on a resident's exposure to COPCs via the dermal contact with water and shower inhalation pathways, as per national USEPA guidance.

### 7.4.1 Groundwater EPCs Calculated using Core of the Plume Data

The refinement process for calculation of the groundwater EPCs for the Core of the Plume evaluation is described below.

#### 7.4.1.1 Selection of COPCs and Data

The groundwater HHRA update identified 30 COPCs, listed in [Table 3-3](#). The 13 COPCs with less than 5% detection frequency, which were not risk drivers in the main risk conclusions (see

**Section 6.3 Risk Assessment Results**), are flagged with a “\*” in [Table 3-3](#) and are not carried through in the Core of the Plume evaluation.

The maximum concentrations for each well were reviewed for each of these COPCs. Based on the distribution of wells in which the largest concentrations were located, the groundwater data from the five wells with the highest concentrations were reviewed for each COPC. For each of these wells, the highest and the second highest detected concentrations were chosen to be included in the Core of the Plume data set. This means that each data set for the calculation of the 95 percent UCLs consisted of no more than the 10 detected highest concentrations for each COPC, in accordance with the guidance (USEPA 2014a).

The groundwater EPCs are presented in Attachment D, [Table D.1](#) for the Fluvial aquifer and [Table D.2](#) for the IAQ. The supporting ProUCL data input and outputs are provided in Attachment D, [Tables D.11](#) through [D.13](#).

#### 7.4.1.2 Exposure Factors & Toxicity Values

The exposure factors applied in the exposure scenarios for a worker and resident's exposure to groundwater remain the same, with the exception of exposure factors that incorporate the EPCs. The calculation of the DA-event from water contact is presented in Attachment D, [Tables D.3](#) and [D.4](#) and the calculation of bathroom air concentrations is in Attachment D, [Tables D.5](#) and [D.6](#).

The toxicity values are the same as those applied in the groundwater HHRA update.

### 7.4.2 Core of the Plume - Fluvial Aquifer

#### 7.4.2.1 Worker

The cumulative cancer risks and non-cancer HIs by exposure pathway for a current on-site worker's exposure to COPCs in the Fluvial aquifer are summarized in [Table 7-5](#) below. Chemical-specific cancer risks and non-cancer HQs are presented in Attachment D, [Table D.7](#).

The total ELCR for a worker's exposure to COPCs in groundwater via tapwater from all pathways is 1.2E-02. The ELCR for groundwater ingestion exposure is 1.1E-02; primary contributors are 1,2,3-trichloropropane, CF and VC. The ELCR for groundwater dermal exposure is 5.3E-04; the primary contributor is 1,2,3-trichloropropane.

The total non-cancer HI is 3.3E+01. The HI for ingestion exposure is 3.1E+01 and the primary contributors are CF, TCE and cis-1,2-DCE. The HI for dermal exposure is 1.5E+00 whose main contributors are CF, TCE and PCE. See [Table 7-2](#).

**Table 7-5 Core of Plume: Worker's Exposure to Fluvial Aquifer Groundwater**

| Exposure Route | Cumulative Cancer Risk | Primary COPCs                                                                                                                                                                                              | Hazard Index | Primary COPCs                                      |
|----------------|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|----------------------------------------------------|
|                | <i>Lifetime</i>        |                                                                                                                                                                                                            |              |                                                    |
| Ingestion      | 1.1E-02                | 1,2,3-trichloropropane (8.3E-03), CF (2.6E-03), VC (3.8E-04), CT (3.7E-05), TCE (3.4E-05), 1,2-dichloroethane (4.3E-06), 1,2-dichloropropane (3.7E-06), PCE (2.2E-06), 1,1,2,2-tetrachloroethane (1.3E-06) | 3.1E+01      | CF (2.4E+01), TCE (4.1E+00), cis-1,2-DCE (1.3E+00) |
| Dermal         | 5.3E-04                | 1,2,3-trichloropropane (4.1E-04), CF (9.8E-05), VC (1.3E-05), CT (4.1E-06), TCE (2.3E-06)                                                                                                                  | 1.5E+00      | CF (8.8E-01), TCE (2.8E-01), PCE (1.2E-01)         |
| <b>Total</b>   | 1.2E-02                |                                                                                                                                                                                                            | 3.3E+01      |                                                    |

#### 7.4.2.2 Resident

The cumulative cancer risks and non-cancer HIs by exposure pathway for a future on-site resident adult and child's exposure to COPCs in the Fluvial aquifer are summarized in [Table 7-6](#) below. Chemical-specific cancer risks and non-cancer HQs are presented in Attachment D, [Table D.8](#).

The total ELCR for a resident's exposure to COPCs in groundwater via tapwater from all pathways is 3.2E-01. The groundwater inhalation pathway is 1.7E-01, the ingestion pathway is 1.3E-01 and the dermal pathway is 1.2E-02; the primary contributors to these pathways are CF, 1,2,3-trichloropropane TCE and VC.

The total non-cancer HI is 6.1E+02 for an adult and 5.9E+02 for a child. The inhalation and ingestion pathways contribute the most to these HIs; TCE, 1,2,3-trichloropropane and CF are the primary contributors. See [Table 7-6](#).

**Table 7-6 Core of Plume: Resident's Exposure to Fluvial Aquifer Groundwater**

| Exposure Route | Cumulative Cancer Risk | Primary COPCs                                                                                                                           | Hazard Index |              | Primary COPCs                                                                                                                                                                                                                      |
|----------------|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|--------------|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | <i>Lifetime</i>        |                                                                                                                                         | <i>Adult</i> | <i>Child</i> |                                                                                                                                                                                                                                    |
| Ingestion      | 1.3E-01                | 1,2,3-trichloropropane (1.2E-01), CF (1.1E-02), VC (6.7E-03), TCE (2.1E-04), CT (1.5E-04)                                               | 8.7E+01      | 1.5E+02      | CF (adult 6.6E+01, child 1.1E+02), TCE (adult 1.2E+01, child 1.9E+01), cis-1,2-DCE (adult 3.5E+00, child 5.8E+00), PCE and VC (adult 2.3, child 1.4), CT (adult 1.0E+00, child 1.7E+00), 2-butanone (adult 7.1E-01, child 1.2E+00) |
| Dermal         | 1.2E-02                | 1,2,3-trichloropropane (1.1E-02), CF (8.2E-04), VC (4.5E-04), CT (3.4E-05), TCE (2.8E-05), PCE (4.5E-06), 1,2-dichloropropane (1.2E-06) | 9.5E+00      | 1.4E+01      | CF (adult 5.8E+00, child 8.7E+00), TCE (adult 1.9E+00, child 2.8E+00), PCE (adult 7.8E-01, child 1.2E+00)                                                                                                                          |

| Exposure Route | Cumulative Cancer Risk | Primary COPCs                                                                                                        | Hazard Index |              | Primary COPCs                                                                                                                                                                                                                                                                                                                                                |

|                | <i>Lifetime</i>        |                                                                                                                      | <i>Adult</i> | <i>Child</i> |                                                                                                                                                                                                                                                                                                                                                              |
| Inhalation     | 1.7E-01                | CF (1.5E-01), VC (2.1E-02), TCE (6.8E-04), 1,2-dichloropropane (3.0E-04), CT (2.6E-04), 1,2-dichloroethane (1.0E-04) | 5.1E+02      | 4.3E+02      | 1,2,3-trichloropropane (adult 2.1E+02, child 1.8E+02), CF (adult 2.0E+02, child 1.7E+02), TCE (adult 8.4E+01, child 7.1E+01), PCE (adult 6.0E+00, child 5.0E+00), 1,2-dichloropropane (adult 5.7E+00, child 4.8E+00), 2-butanone (adult 2.5E+00, child 2.1E+00), 1,2-dichloroethane (adult 1.6E+00, child 1.3E+00), CT and VC (adult 1.2E+00, child 1.0E+00) |
| <b>Total</b>   | 3.2E-01                |                                                                                                                      | 6.1E+02      | 5.9E+02      |                                                                                                                                                                                                                                                                                                                                                              |

### 7.4.3 Core of the Plume - IAQ

#### 7.4.3.1 Worker

The cumulative cancer risks and non-cancer HIs by exposure pathway for a current on-site worker's exposure to COPCs in the IAQ are summarized in [Table 7-7](#) below. Chemical-specific cancer risks and non-cancer HQs are presented in Attachment D, [Table D.9](#).

The total ELCR for a worker's exposure to COPCs in groundwater via tapwater from all pathways is 2.7E-05. The ELCR for groundwater ingestion exposure is 2.3E-05; primary contributors are VC, TCE and CF. The ELCR for groundwater dermal exposure is 1.1E-06, with the primary contributors being VC, TCE and PCE.

The total non-cancer HI is one. See [Table 7-7](#).

**Table 7-7 Core of Plume: Worker's Exposure to IAQ Groundwater**

| Exposure Route | Cumulative Cancer Risk | Primary COPCs                              | Hazard Index | Primary COPCs |
|----------------|------------------------|--------------------------------------------|--------------|---------------|
|                | <i>Lifetime</i>        |                                            |              |               |
| Ingestion      | 2.3E-05                | VC (1.5E-05), TCE (5.0E-06), CF (1.3E-06)  | 9.6E-01      | --            |
| Dermal         | 1.1E-06                | VC (5.3E-07), TCE (3.4E-07), PCE (1.7E-07) | 8.7E-02      | --            |
| <b>Total</b>   | 2.4E-05                |                                            | 1.0E+00      |               |

#### 7.4.3.2 Resident

The cumulative cancer risks and non-cancer HIs by exposure pathway for a future on-site resident adult and child's exposure to COPCs in the IAQ are summarized in [Table 7-8](#) below. Chemical-specific cancer risks and non-cancer HQs are presented in Attachment D, [Table D.10](#).

The total ELCR for a resident's exposure to COPCs in groundwater via tapwater from all pathways is 1.4E-03. The groundwater inhalation pathway via showering contributes the most to

this risk, with an ELCR of 1.1E-03; the primary contributors are VC, TCE and CF. The ingestion pathway has an ELCR of 3.1E-04, its primary contributors are VC and TCE. The dermal pathway has an ELCR of 2.5E-05, its primary contributors are VC, TCE and PCE.

The total non-cancer HI is 1.8E+01 for an adult and 1.8E+01 for a child. The groundwater inhalation pathway contributes the most to these HIs with an HI at 1.5E+01 for an adult and HI of 1.3E+01 for a child; PCE and TCE are the primary contributors. The groundwater ingestion pathway for an adult has a HI of 2.7E+00; the child has a HI of 4.5E+00, also resulting from potential exposure to TCE and PCE. See [Table 7-8](#).

**Table 7-8 Core of Plume: Resident's Exposure to IAQ Groundwater**

| Exposure Route | Cumulative Cancer Risk | Primary COPCs                                              | Hazard Index |              | Primary COPCs                                                          |
|----------------|------------------------|------------------------------------------------------------|--------------|--------------|------------------------------------------------------------------------|
|                | <i>Lifetime</i>        |                                                            | <i>Adult</i> | <i>Child</i> |                                                                        |

#### 7.4.4 Core of the Plume Risk Summary

Results of this sensitivity analysis indicate that there may be potential for unacceptable risk to current/future on-site workers and future on-site residents from exposures to COPCs in the Fluvial aquifer and IAQ. As noted above, the MAQ was not evaluated as there are limited data and the results of a Core of Plume analysis would have been identical to the initial results.

In comparison to the results presented in [Sections 6.3.1](#) and [6.3.2](#), the cancer risks in the Fluvial aquifer using the Core of the Plume data set are two orders of magnitude greater; the non-cancer HIs are an order of magnitude higher. In the IAQ, the cancer risks and non-cancer HIs are one order of magnitude greater.

As this sensitivity analysis utilized the highest concentrations in the data set to represent the core of contamination in each aquifer, it is a worst-case scenario and may not represent realistic exposure. This is further supported by the presence of the LUCs at DDMT that limit exposure to groundwater.

## 8 Review of 2000 Soils HHRA

### 8.1 Overview and Soils HHRA Methodology

#### 8.1.1 Overview

HDR has conducted a review of the soil component of the 2000 MI RI HHRA for FU1 through FU6 to determine if, under current guidance and toxicity values, the conclusions of the Soils HHRA are still valid and whether or not the remedial actions completed since that time are protective. The FUs, which were designated based on operational history, expected use and location, are shown on [Figure 1-1](#). Recommendations are provided regarding whether or not the soil evaluations need to be updated.

The Soils HHRA included an assessment of human health impacts from surface and subsurface soil; HDR's review includes assessment of the methodology and a comparison of analytical data for COPCs to current risk-based human health screening levels.

#### 8.1.2 Soils HHRA Methodology

The 2000 MI RI Soils HHRA had four primary components:

1. Identify COPCs – Analytical data generated from the 2000 MI RI were compared to the USEPA Region 3 Risk-Based Concentrations (RBCs) for soil (target risk of 1E-06 and target HQ of 0.1; now incorporated into the nationwide USEPA RSLs) to determine COPCs in the 2000 HHRA, which is described in Section 7.3 and Appendix D, Table D.1 of that report. Site-wide COPCs for soil were determined to be VOCs, SVOCs, pesticides, PCBs and metals.
2. Exposure assessment – COPC migration pathways, potential receptors and magnitude of exposure to COPCs were determined. EPCs were calculated using 95 percent UCLs and incorporated in the exposure doses. Exposure doses were calculated for each COPC and complete exposure pathway. The Soils HHRA evaluated a maintenance worker, lumberyard/factory worker, utility worker, landscaper, industrial/commercial worker, shelter/transient resident, long-term resident and recreator.
3. Toxicity assessment – Toxicity values and potential health effects of the COPCs were identified.
4. Risk characterization – Cancer risks and HQs were calculated for each COPC using the exposure doses and toxicity values. The COPCs that were determined to be COCs in this step, as they contributed the most to the cancer risks and HQs, and were carried through in the MI ROD were lead, arsenic and dieldrin. Polycyclic aromatic hydrocarbons (PAHs) were not carried forward as high PAH detections were associated with transportation infrastructure (CH2M HILL 2001).

The risks from these COCs were largely addressed in removal actions performed prior to completion of the 2001 MI ROD, at locations shown on [Figure 4-2](#). These actions and resulting

residual soil contaminant concentrations were reflected in the EPCs calculated for each FU and other screening sites included in the Soils HHRA.

Two additional soil removal actions were completed after the Soils HHRA; one adjacent to Building 949 in FU4, where surface soil containing elevated concentrations of chromium and lead adjacent to Building 949 in FU4 was removed in 2001; and the second at BRAC Parcels 35 & 28 in the southwest corner of FU3, where contaminated soils containing elevated metals and PAHs were removed in 2000.

While the overall methodology in the Soils HHRA was relevant and appropriate, changes in some details of the methodology have changed since 2000, as noted in [Section 6.3.4](#). These changes relate to exposure factors, evaluation of inhalation risks, toxicity values and the effects of chemicals now being identified as having a MMOA.

One change relevant to DDMT soils is that the methodology for applying the toxicity values for both dioxins and PAHs has changed. The benzo(a)pyrene (BaP) cancer toxicity value is now applied as the relative value for other PAHs, modified by multiplying the toxicity equivalence factors (TEFs) for each PAH (e.g., for benzo(b)fluoranthene, the oral slope factor of 1 (mg/kg-day)<sup>-1</sup> for BaP, multiplied by the TEF of 0.1). These TEFs have been incorporated in the current RSL values, which are presented in Attachment F [Table 1a](#), and are further described in the USEPA *RSL User's Guide*, *Section 2.3.5* (USEPA 2019b) and USEPA *Provisional Guidance for Quantitative Risk Assessment of Polycyclic Aromatic Hydrocarbons*, Table 7 (USEPA 1993). Similarly, TEFs for the dioxins, furans and dioxin-like PCBs are now applied, with a range of 0.0001 to 1 (Van den Berg et al. 2006; USEPA 2019b) used as a multiplier for the 2,3,7,8-tetrachlorodibenzo-pdioxin (TCDD) value.

## 8.2 Soils HHRA Issues Considered in Current Review

### 8.2.1 Background Concentrations

The 2000 MI RI included a determination of background concentrations of contaminants in order to evaluate whether site operations or releases of hazardous materials contributed to contaminant concentrations exceeding background levels. The background levels were included as a criterion in Section 7.3 of the 2000 MI RI and in the FU-specific COPC selection tables; however, review of the tables indicates that no contaminants were eliminated from the COPC list based on background levels.

Background soil samples, 22 surface soil and 22 subsurface soil, were collected at the Depot perimeter and at off-site locations to assess the potential impact of Depot operations on contaminant concentrations in soil (CH2M HILL 1998). Data were compared to the USEPA Region 3 RBCs; exceedances were identified for metals, PAHs and dioxin/furans.

- The individual constituent background levels in soil, provided in 2000 MI RI [Tables 3-10](#) and [3-11](#), are included in Attachment F.
- Arsenic had a range of 4.2 to 27.7 mg/kg in surface soil; the background value was initially noted as 21.8 mg/kg, but was modified to 16.5 mg/kg after outlier removal.

Arsenic had a range of 3.1 to 14.1 mg/kg in subsurface soil; the background value was 17.0 mg/kg.

- Lead had a range of 11.7 to 73.3 mg/kg in surface soil; the background value was initially noted as 42.6 mg/kg, but was modified to 30 mg/kg after outlier removal. Lead had a range of 6.9 to 22.7 mg/kg in subsurface soil; the background value was 23.9 mg/kg.
- Dioxins and furans were detected in most background soil samples, generally at higher concentrations at the surface than at depth and included octa- and hepta-isomers, indicating an atmospheric deposition source.

Surface soil concentrations for metals, VOCs, SVOCs, pesticides and PCBs were higher at the Depot perimeter than at off-site locations. This difference is noted in the 2000 MI RI as likely being a result of the industrial vs. residential and recreational land uses in these locations. The 2000 MI RI also states that higher concentrations for xylene and phthalates at the Depot perimeter likely result from off-site vehicular traffic around the facility.

The maximum arsenic concentration detected in non-background samples at the MI was 66.3 mg/kg in surface soil and 34.2 mg/kg in subsurface soil, as noted in Table 6-4 of the 2000 MI RI. The concentrations are within the range of background concentrations identified for the site and in the following references:

- The range of background arsenic concentrations in soil for the Eastern United States is noted as being 1 to 73 mg/kg, with an arithmetic mean of 7.5 mg/kg in a United States Geological Survey publication, *Selenium, Fluorine and Arsenic in Surficial Materials of the Conterminous United States* (Shacklette et. al. 1974).
- A 2003 study entitled *Soil Background Supplemental Data Set for the East Tennessee Technology Park, Oak Ridge, Tennessee* indicated the range of background concentrations was 0.77 to 15 mg/kg, with a 95 percent UCL of 14.95 mg/kg (Bechtel Jacobs 2003).
- *An Analysis of Soil Arsenic Records of Decision* documented arsenic cleanup levels at Superfund sites; the concentration range was 3.2 to 20 mg/kg in soil where attainment of background concentrations was used as the basis for the cleanup, and the range was 2 to 305 mg/kg including both background- and risk-based goals (Davis et. al. 2001).

## 8.2.2 Dioxins/Furans

### 8.2.2.1 Removal Action

Wooden pallets were treated with PCP at the MI during the 1950s; operations were discontinued in 1971. Wood pallets were treated at the PCP Dip Vat Area and the Underground PCP Tank Area (Screening Sites 42 and 43). The pallets were dried near Screening Site 46 (approximately 115 ft south of Building 720 and 125 ft west of 6<sup>th</sup> Street). The general area, located in FU4, is shown on [Figure 4-2](#). A removal action was conducted in 1985; background information and the removal action are described in the *Summary Report, On-site Remedial Activities at the Defense Depot Memphis* (OHM 1986).

Analysis of a sample of the liquid taken from the dip vat by DLA personnel revealed the presence of PCP. Further analytical investigation by U.S. Army Environmental Hygiene Agency investigators of the liquid in Building 737 revealed the presence of appreciable levels of higher chlorinated dioxins and furans (e.g., penta-, hexa-, hepta-, and octa-isomers). Chlorinated dioxins and furans are contaminants often produced in the manufacture of the wood preservative PCP and other chlorinated organic compounds.

The liquids and sludge within the PCP Dip Vat tank were removed and placed in 55-gallon drums. After initial attempts to decontaminate the structure, Army and Tennessee Department of Health and Environment (TDHE, now TDEC) directed the building be disassembled for disposal. The 12,000 gallon PCP storage tank, which had only a small amount of oily liquid remaining, was excavated; the tank was then cut in pieces, sand blasted and pressure-washed prior to placement in a roll-off for storage prior to disposal. The tank was determined to be structurally sound but leakage was apparent at joints in the piping to the dip vat based on observations during removal and presence of stained soil.

Following removal of the structure, soil samples were collected from borings on a grid within the dip vat and storage tank area to develop a depth and perimeter profile of the planned excavation. The target soil cleanup level of 200 micrograms per kilogram ( $\mu\text{g}/\text{kg}$ ) of total dioxin and furan isomers was established in consultation between Army, USEPA and TDHE. Soil contamination above the cleanup level was observed to a depth of 25 ft at the north end of the dip vat structure. Soil was excavated to average depths of 14 ft at the PCP storage tank; 10 ft beneath the dip vat, adjacent rollers and pump house; and 2 to 5 ft in adjacent areas. Soil with total dioxin and furan concentrations above the cleanup level was left in place below the excavated depth at the north end of the dip vat structure. Adjacent areas east and north of the excavation area had 3 to 6 inches of soil removed and approximately 2 inches of gravel placed for cover.

The excavated soil was sampled to determine residual contamination. Soil with total dioxin and furan concentrations above the cleanup level was placed in containers and stored for off-site disposal. Soil with concentrations less than the cleanup level was used for backfill along with clean soil from off-site sources. The excavated area was backfilled and covered with gravel. In spring 1988, the contaminated soil and debris was transported and disposed at a hazardous waste disposal facility following approval by USEPA and TDHE.

In addition to its use for wood treatment, the dip vat liquid was also suspected of having been mixed with waste oil and sprayed in the surrounding area for dust control. Samples were collected in six areas where spraying was suspected; individual soil samples were composited for each area and analyzed for TCDD. The sample for Area 2 contained TCDD at  $5.6 \mu\text{g}/\text{kg}$ ; the other sample results for TCDD were  $<0.05$  to  $0.85 \mu\text{g}/\text{kg}$ . The EPA residential clean-up level at the time was reported to be  $1 \mu\text{g}/\text{kg}$ . Area 2 was divided into six sub-areas and composite samples were collected from each sub-area at depth ranges of 0 to 4 inches and 4 to 8 inches; the samples were analyzed for TCDD and for other dioxin and furan isomers. The sample results for TCDD were below the cleanup level at concentrations of  $<0.05$  to  $0.5 \mu\text{g}/\text{kg}$ ; other dioxin and furan isomers were detected at higher concentrations and the shallow samples had

higher concentrations than the deeper samples. The maximum concentrations for the other analytes in the shallow samples were polychlorinated dibenzo-p-dioxin at 2.2 µg/kg, hexachlorodibenzo-p-dioxin at 10 µg/kg, heptachlorodibenzo-p-dioxin at 230 µg/kg, octachlorodibenzo-p-dioxin at 1600 µg/kg, 2,3,7,8,-tetrachlorodibenzofuran (TCDF) at 0.3 µg/kg, polychlorinated dibenzofuran at <0.1 µg/kg, hexachlorodibenzofuran at 23 µg/kg, heptachlorodibenzofuran at 190 µg/kg and OCDF at 230 µg/kg. The Army, in consultation with TDHE and USEPA, had 6 to 12 inches of gravel placed over the impacted area of 3.5 acres north of Building 737.

#### 8.2.2.2 Land Use Restrictions

Due to the presence of soils contaminated with dioxins and furans remaining in place, requirements were established for ground cover and access.

1. TDHE letters dated 26 September 1985 and 16 October 1985 addressed the area suspected of having waste oil with PCP sprayed for dust control and TCDD concentrations below the EPA action level (5-6 parts per billion [ppb]). The October letter stated conditions for the agreed approach to place 6 to 8 inches of compacted gravel:
  - a. The graveled area must be placed "off limits" to any and all vehicular traffic.
  - b. The area must be indicated as a "non-use" area on the facility development plat.
  - c. Future plans for utilization of the area must be approved by the Department.
  - d. Prior to placement of gravel the entire area should be sprayed with water to prevent dusting.
2. Restrictions on the PCP Dip Vat area are stated in the MI NLUR recorded on 26 January 2005. The MI NLUR states two site-wide restrictions and one restriction for the PCP Dip Vat area. The site wide restrictions are: No residential land use or other child-occupied facilities, and No production/ consumptive use of groundwater or drilling groundwater wells on the MI. The PCP Dip Vat area restriction is:
  - a. No digging in soil material 10 ft below the land surface due to elevated PCP soil concentrations at the Former PCP Dip Vat Area (Solid Waste Management Unit [SWMU] 42) and the Former Underground PCP Tank Area (SWMU 43). A map with surveyed coordinates of the 'no dig' areas was included in the NLUR.
3. The MI LUCIP (CH2M HILL 2004b) references the MI NLUR but does not mention the PCP Dip Vat restrictions.

#### 8.2.2.3 2003 Investigation

Additional investigation was performed in 2003 as required by TDEC for closure of SWMU 42, Former PCP Dip Vat Area. The objective was to evaluate the presence or absence of PCP and PCP degradation products in soil; the PCP degradation products are 2,3,4,6-tetrachlorophenol, 2,4,5-trichlorophenol (TCP), 2,4,6-TCP, dichlorophenol, 2-chlorophenol, and phenol. In addition four samples were collected for analysis of dioxins and furans. The report (CH2M HILL 2004b) summarizes previous investigations and presents the 2003 soil testing results and results of fate

and transport modeling for SWMU 42. The report states the area of soil contamination north of Building 737 was due to its use for drying the pallets rather than to use the waste oil with PCPs for dust control. Also, the surface of the former PCP Dip Vat, the PCP UST and the area to the east of the former dip vat had been covered by concrete at some time after the removal action. Soil samples were collected from four borings within the limits of the 1985 soil excavation and three borings to the southeast near the PCP UST excavation.

Of the detected dioxins and furans, the higher chlorinated, more persistent isomers were the most commonly detected. Only TCDD was reported to have an EPA Region 9 PRG of 0.016 mg/kg for industrial direct contact; the concentration of TCDD in all samples was below this value.

Concentrations of dioxins and furans for each sample were transformed into a total TCDD toxicity equivalent (TEQ) concentration. The toxic equivalency factor (TEF), which relates the compound to the toxicity of TCDD TEFs were obtained from the 1998 World Health Organization values (Van de Berg, et al. 1998). The individual TEQ values were then summed to determine the total TEQ. The TCDD TEQ background values at the MI are 0.01 µg/kg in surface soil and 0.006 µg/kg in subsurface soil (CH2M HILL 2000). TEQ values slightly exceeded these background values at sample points SB-114 (zero to 6 ft bgs) and SB-115 (6 to 13 ft bgs). The USEPA action level for the TCDD TEQ was 1 µg/kg for residential soils and 5 µg/kg to 20 µg/kg for industrial soils (EPA 1998a). TEQs for all samples were below 1 µg/kg.

TDEC approved the PCP Dip Vat Closure in a letter dated 15 July 2008.

#### 8.2.2.4 Conclusions

There were no soil screening levels for dioxins/furans available at the time the 2000 MI RI was completed. For this review, the maximum detected dioxin and furan congener-specific concentrations and the calculated TCDD equivalent surface soil concentrations ([Table 4a](#) in Attachment G) were compared current USEPA Industrial Soil RSLs. The TCDD equivalent data incorporates recognized TEFs that allow an estimation of the overall toxicity of mixtures of dioxins and furans. The data indicated exceedances for TCDD equivalent data in soil samples from FU3 and FU4 and for congener-specific concentrations in FU4.

Dioxin and furan concentrations in background samples are shown on [Table 3-10](#) in Attachment F. The range of background concentrations for TCDD equivalents is 0.001 to 0.02 µg/kg in surface soil, less than 0.001 to 0.01 µg/kg in subsurface soil, less than 0.001 to 0.009 µg/kg in sediment and less than 0.001 to 0.03 nanograms per liter (ng/L) in surface water. (The minimum concentration detected in background subsurface soils, sediment and surface water samples is shown as 0.000 in the 2000 MI RI report.) The background values are 0.010 µg/kg in surface soil, 0.006 µg/kg in subsurface soil, 0.009 µg/kg in sediment and 0.018 ng/L in surface water. The Industrial soil RSL for TCDD equivalent in soil is 0.022 µg/kg, which is greater than the background value.

In FU3, the calculated, maximum concentration in surface soil for TCDD equivalent is 0.0103 µg/kg, slightly above the background value, but less than the Industrial RSL. There are

exceedances of other concentrations of dioxins/furans when compared to the Industrial RSL for TCDD equivalent (e.g., octachlorodibenzo-p-dioxin). The concentrations of dibenzofuran are less than its Industrial RSL of 150 µg/kg. The maximum concentration in subsurface soil for TCDD equivalent is 0.013 µg/kg (MI RI Table 18-6), which is also less than the Industrial Soil RSL.

In FU4, the calculated, maximum concentration for TCDD equivalent is 0.083 µg/kg, approximately an order of magnitude greater than the background value and slightly higher than the Industrial RSL. See Attachment G, [Table 4a](#). In addition, the maximum concentrations for 10 dioxin/furan congeners are greater than the Industrial Soil RSLs for TCDD equivalent. The maximum concentration in subsurface soils for TCDD equivalent is reported as 13 µg/kg (MI RI Table 22-7); given the range of other values for the UCLs and EPCs in the 2000 MI RI is orders of magnitude lower, the reported concentration is considered to be a typographical error. Additional sampling to substantiate the maximum concentration for TCDD equivalent in subsurface soils is planned, as discussed in [Section 8.5](#).

There are no exceedances of the USEPA Industrial Soil RSLs in the other FUs (Attachment G, [Table 4a](#)).

There are no exceedances of human health screening levels in sediment, as there are no generic human health sediment criteria. These are generally to be developed on a site-specific basis and that was not done as part of the 2000 MI RI or included in the scope of this review. Surface water detected concentrations were compared to their respective state and USEPA water quality criteria; including human health criteria that are based on the consumption of both water and organisms and reflect surface water designations, e.g., use as a domestic water supply or for contact recreation. Potential ecological risk due to dioxins/furans in sediment and surface water is discussed in [Section 9](#).

Due to the detection of dioxin/furan concentrations at levels above background and/or screening levels in some samples within FU3 and FU4, the protocol included in the April 2013 *Tri-Service Environmental Risk Assessment Workgroup Questions/Answers on Dioxin* (TSERAWQ, 2013) should be used as guidance in determining the need for further assessment. This document can be found at <https://clu-in.org/download/contaminantfocus/dioxins/dioxin-fags-2013.pdf>.

The document states that environmental investigations should focus on the potential for direct-contact pathways for human and ecological receptors, as dioxins are generally not sufficiently soluble to pose a leaching threat to underlying groundwater. Given that the Dip Vat Area, where dioxin exceedances were identified also has LUCs for PCP, which can migrate in groundwater, both should be considered in a coordinated manner if further evaluation of FU3 and FU4 is performed.

The document includes the following considerations regarding the need for further assessment; the applicability to DDMT is added in the underlined text.

- *Under which circumstances should I consider sampling and analysis for dioxin at my site?*

Sampling and analysis for dioxins should be considered when the CSM and historical information indicates a release from DOD operations may have occurred.

This appears to be the case at DDMT, e.g., in the Dip Vat Area.

- *Does the TEQ method change for non-cancer risks?*

Most previous site-specific dioxin risk assessments focused upon cancer risks only. The publication of a non-cancer reference dose now allows for these health risks to be calculated. The standard practice of using TCDD as the reference congener to assess the cancer and non-cancer toxicity of dioxins as toxicity equivalents has not changed. The TEQ method has been in use for some time and the new toxicity values do not change its implementation in risk assessments.

At this juncture, the groundwater HHRA included in this document has been updated to address non-cancer effects; soils have not yet been evaluated in an updated quantitative risk assessment.

- *Under which circumstances should I consider sampling and analysis for dioxin at my site?*

Sampling and analysis for dioxins should be considered when the CSM and historical information indicates a release from DOD operations may have occurred.

This appears to be the case at DDMT, e.g., in the Dip Vat Area.

- *What are the major risk management decisions potentially affected?*

A decision on whether to reassess where dioxin has been or continues being managed with remedial action. *Determinations of whether to characterize possible dioxin contamination at sites should be made on a site-specific basis, considering the CSM and whether DOD operations might have led to dioxin contamination above background levels.*

At DDMT, it appears that the Dip Vat area, in particular the use of PCP has resulted in soil contamination with dioxins.

- *If I cleaned up dioxin in the past do I need to evaluate the protectiveness of that cleanup? Do I do this now or during a periodic- or 5-year review?*

Sites with remedies in place where dioxins are contaminants of concern may in some cases have to be re-evaluated. Assessment should take place as part of the regular 5-year or *periodic review process*.

The HHRA and SLERA update and reviews are part of a periodic review process, a protectiveness review is appropriate at this juncture.

The *Fact Sheet on the Management of Dioxin Contaminated Soils* (USEPA 2011c) is meant to assist site managers in determining whether dioxin-contaminated soils are best managed on or off site and should be considered in making a determination on the need and type of remedial action, particularly as it relates to Land Disposal Restrictions (LDRs). LDRs are applicable to dioxin-contaminated soils when they are: generated/excavated and placed in a land disposal

unit. If the dioxin- contaminated soils are not removed from the land, LDRs do not apply. See <https://semspub.epa.gov/work/HQ/174546.pdf>

Also note that the Dioxin Listing Rule (50 FR 1987) designates certain wastes containing particular chlorinated dibenzo-p-dioxin, chlorinated dibenzofurans and chlorinated phenols as acute hazardous waste. This would include PCP, which is suspected of being the primary source of dioxins.

### 8.3 Review of Current Conditions using 2000 MI RI Data by FU

The 2000 MI RI conducted site-specific HHRAs with high-end potential exposures and also conducted FU-wide HHRAs using reasonable maximum exposures.

For the site-specific HHRAs, a surrogate site was evaluated instead of evaluating the approximately 80 sites identified within the MI. Depending on the exposure scenario evaluated, a surrogate site or a single highest concentration data point for worst-case exposure concentrations was used to estimate risk for a future hypothetical resident. An exposure unit for a resident is assumed be a 0.5-acre lot, represented by the highest preliminary risk evaluation (PRE) data point within the FU. A maintenance worker's exposure unit is the entire area within an FU, while an industrial worker exposure is assumed to be a smaller exposure unit, represented by a surrogate site. Table 7-1 in the 2000 MI HHRA presents the rationale for the surrogate site and residential risk data point selection, and a list of the various exposure units for each of the FUs within the MI.

For the FU-wide HHRA, the data were combined from samples collected within the FU during three sampling events at BRAC parcels and the screening and RI sites. The sampling consisted of 580 surface soil samples collected using a clean stainless-steel hand auger or scoop to retrieve soil from ground surface to 2 ft bgs and 40 percent of these samples were used to determine nature and extent of contamination. There were 427 subsurface soil samples collected from 154 vertical soil borings that were installed by either direct-push, hollow-stem auger or rotasonic methods and 65 percent were used to determine the presence of COPCs in the area. The FU-wide HHRAs also evaluated residential and industrial land use scenarios.

[Table 1a](#) in Attachment F presents the EPCs at 0-2 and 0-10 ft bgs that were used in the FU-wide HHRAs. Comparison of the FU-wide EPCs and the current USEPA Residential and Industrial Soil RSLs (at a target cancer risk of 1E-06 and target hazard quotient of 0.1) was performed to evaluate whether or not the conclusions of the Soils HHRA remain valid (see Attachment F, [Table 1a](#)). A majority of the FUs are designated for industrial use and the subsequent evaluation considers only the Industrial Soil RSLs in the comparison to EPCs. Limited areas of FU-6 are designated as unrestricted use and unrestricted exposure (UU/UE) and in those areas, the evaluation considers both the Industrial and Residential Soil RSLs in the comparison to EPCs.

Table 1b in Attachment F presents screening risks and hazards that were calculated using the EPCs and RSLs (at a target cancer risk of 1E-06 and target hazard quotient of 1, which is the point of departure for acceptable hazards), expressed in the equations below:

$$\text{Screening Cancer Risk} = \frac{EPC}{RSL_{cancer}} \times \text{Target Risk}$$

$$\text{Screening Noncancer Hazard} = \frac{EPC}{RSL_{noncancer}} \times \text{Target Hazard Quotient}$$

Table 1c in Attachment F presents a summary for each FU of the cumulative risk and hazard index (HI), which are the sum of the individual chemical-specific cancer risks and separately, the sum of the individual chemical-specific hazards.

### 8.3.1 FU1

The comparison of detected concentrations to RSLs within FU1 indicates that in both shallow (0-2 ft deep) and deeper (0-10 ft) soils, total petroleum hydrocarbons (TPH), benzo(a)pyrene, dieldrin, Aroclor 1260 and arsenic, were detected at levels exceeding their respective Industrial RSLs. Dibenz(a,h)anthracene exceeds its Industrial RSL in the shallow soils and meets its Industrial RSL in the deeper soils. The cumulative risks and HI are within the acceptable risk range and less than the acceptable limit of one, respectively, in both the shallow and deep soils. The cumulative cancer risk is 2.8E-05 and HI is 0.32 in shallow soils; the cumulative cancer risk is 5.3E-05 and HI is 0.39 in the deeper soils.

### 8.3.2 FU2

Only shallow (0-2 ft bgs) soil data are available for this area. The inorganic constituents, arsenic and chromium, exceed their respective Industrial RSL in surface soil, as does dieldrin. Total chromium concentrations exceed hexavalent chromium screening values, but not trivalent values. The cumulative risks are within the acceptable risk range and the HI values are less than the acceptable limit of one in the shallow soils, as shown on Table 8-1.

**Table 8-1 Cumulative Cancer Risks and Hazard Index Values in FU-2 Surface Soils**

| Functional Unit Area | Cumulative Cancer Risk | Hazard Index |
|----------------------|------------------------|--------------|
| FU-2 Ballpark        | 1.5E-05                | 0.18         |
| FU-2 Golf Course     | 3.6E-05                | 0.41         |
| FU-2 Playground      | 1.2E-05                | 0.19         |
| FU-2 Surface Soil    | 2.4E-05                | 0.26         |

### 8.3.3 FU3

Within FU3, TPH, arsenic and chromium exceed their respective Industrial RSLs in both shallow (0-2 ft deep) and deeper (0-10 ft) soils. As in other FUs, total chromium concentrations exceed

hexavalent chromium screening values, but not trivalent values. The cumulative risks are within the acceptable risk range and HI values are less than or meet the acceptable limit of one. The cumulative cancer risk is  $6.3\text{E-}06$  and HI is 1.1 in the shallow soils; the cumulative cancer risk is  $5.2\text{E-}06$  and HI is 0.90 in the deeper soils. Parcels 35 & 28 within FU3 were subject to the post-RI soil removal action, described in [Section 8.4.2](#).

#### 8.3.4 FU4

Within FU4, TPH, arsenic, chromium and dioxins exceed the Industrial RSLs in both shallow and deeper soils. Dieldrin and Aroclor 1260 exceeds the Industrial RSL in the shallow soils only. Total chromium concentrations exceed hexavalent chromium screening values, but not trivalent values. The cumulative risks are within the acceptable risk range; however, the HI values are greater than one. The cumulative cancer risk is  $3.7\text{E-}05$  and HI is 4.2 in the shallow soils whereas the cumulative cancer risk is  $5.0\text{E-}05$  and HI is 4.7 in the deeper soils; the primary contributor is dioxin. Building 949 in FU4 was subject to a post-RI soil removal action, described in [Section 8.4.1](#).

#### 8.3.5 FU5

Within FU5, dieldrin and arsenic exceed the Industrial RSLs within shallow and deeper soils. Benzo(a)pyrene exceeds its Industrial RSL in the shallow soils and total chromium only exceeds the hexavalent screening value in the deeper soils. The cumulative risks are within the acceptable risk range; HI values are less than one. The cumulative cancer risk is  $1.9\text{E-}05$  and HI is 0.11 in the shallow soils; the cumulative cancer risk is  $1.4\text{E-}05$  and HI is 0.13 in the deeper soils.

#### 8.3.6 FU6

Within FU6, dieldrin, Aroclor 1260 and arsenic exceed the Industrial RSLs in both shallow and deeper soils; benzo(a)pyrene exceeds its Industrial RSL in shallow soils only. The cumulative risks are within the acceptable risk range and the HI values are less than one. The cumulative cancer risk is  $2.4\text{E-}05$  and HI is 0.11 in the shallow soils; whereas the cumulative cancer risk is  $2.0\text{E-}05$  and HI is 0.074 in the deeper soils.

As there are limited areas of FU-6 that are designated as UU/UE, as shown on [Figure 4-2](#), the shallow soil EPCs in FU-6 were also compared to the Residential RSLs. The EPCs of benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, indeno(1,2,3-cd)pyrene, dieldrin, Aroclor 1260 and arsenic in the shallow soils exceed their Residential RSLs. The cumulative risk of  $1.5\text{E-}04$  exceeds the acceptable risk range and the HI of 1.4 exceeds the threshold of one; the primary contributors are PCB Aroclor 1260, benzo(a)pyrene, dieldrin and arsenic. Most of the data incorporated in the EPCs were collected from areas outside of the UU/UE area (see MI RI Figure 28-2 and Table 28-2) to evaluate historical sources of contamination in those areas, e.g., pesticides, PAHs and PCBs. Therefore, there is uncertainty in using these data to evaluate potential residential risks and hazards in this portion of FU-6.

## 8.4 Review of Removal Actions Performed After 2000 MI RI in Current Conditions

Figure 4-2 shows the FU boundaries and the soil removal actions on the MI, including those completed after the 2000 MI RI. In order to provide a more accurate characterization of potential risks remaining at the site, the post-RI removal actions were reviewed.

### 8.4.1 Removal Action - Building 949 in FU4

Lead concentrations in soil at the southeastern corner of Building 949 exceeded industrial worker health-protective standards. This building is a fabric-tension structure used to temporarily store steel and tents. The removal action, described in *Remediation Report, Removal Action at Building 949* (Jacobs Federal Programs 2002), consisted of three rounds of excavation:

- Soil was initially excavated to a depth of 1 ft in the area shown on remediation report Figure A-1, provided in Attachment F (Building 949). Post-excavation samples had elevated levels of both lead and chromium; lead concentrations at three locations exceeded the industrial cleanup level of 1,536 mg/kg and total chromium concentrations at nine locations exceeded the industrial cleanup level of 450 mg/kg.
- The first over-excavation (Figure A-2 in Attachment F) extended a portion of the excavation to a depth of 2 ft and widened the excavated area further to the south and east of Building 949. Post-excavation samples exceeded the industrial cleanup levels for lead at one location and chromium at four locations.
- A second over-excavation (Figure A-3 in Attachment F) deepened a portion of the excavation to the south of Building 949 to 2 ft; reported results were below the respective lead and chromium cleanup levels at the time and the soil remediation was considered complete.
- The ground surface was restored with crushed rock to original grade following completion of the removal action.

Remediation goals in the remedial action report were based on 2000 USEPA Region 9 Preliminary Remediation Goals (PRGs, now incorporated into the USEPA RSLs) for Industrial use: 1,536 mg/kg for lead and 450 mg/kg for chromium. Review of the final confirmation sample results indicates that lead concentrations are below the PRG, but chromium concentrations are greater than the PRG in two samples (547 mg/kg at 949B-2 and 512 mg/kg at 949B-5).

The final confirmation sample results were also compared to the USEPA Industrial Soil RSLs (target cancer risk of 1E-06 and HQ of 0.1) for chromium and lead (Table 2 in Attachment F). Lead results are below the Industrial RSL of 800 mg/kg. Total chromium results exceed the hexavalent chromium Industrial RSL of 6.3 mg/kg, but not the Industrial RSL value of 180,000 mg/kg for trivalent chromium.

### 8.4.2 Removal Action - Parcels 35 & 28 in FU3

BRAC Parcels 35 & 28 were used for painting, sandblasting and plating operations and for storage of acids, paints, and cleaning solvents, respectively. Metals were detected at elevated concentrations in areas associated with plating shop operations (i.e., Sites 31, 32, and 33) in Parcel 35. The removal action was conducted to address elevated lead concentrations. The removal action was described in *Remediation Report, Removal Action in Parcels 35 and 28 (Old Paint Shop and Maintenance Area)* (Jacobs-Sverdrup 2000):

- Excavation was completed to 1 ft in multiple locations as part of overall building demolition, underground storage tank (UST) removal and soil cleanup within FU3. Excavation Area A was located adjacent to Perry Road and Excavation Area B encompassed seven separate areas near Buildings 1084, 1087, 1088 and 1089. The excavations were all dug to a depth of 1 ft bgs; additional excavation was completed in a trench along 25<sup>th</sup> Street and continuing through nearby sections of FU3. The areas excavated are shown on [Figure A-1](#) of the removal action report, provided in Attachment F (Parcels 35 & 28).
- The excavated areas were backfilled with “general fill” and completed with grass seed or with 6 inches of aggregate, as noted on [Figure A-1](#) in Attachment F (Parcels 35 & 28).

The reported confirmation sample data for the excavations (Table B-2 for Area B, Table B-4 for Trench Area) were compared to the USEPA Industrial RSLs in this review. The original remediation goals based on 2000 USEPA Region 9 PRGs are also shown ([Tables 3 and 4](#) in Attachment F).

The data from the removal actions indicate that arsenic remains at concentrations exceeding the screening level in place at that time (Industrial RSL of 20 mg/kg), and the current Industrial RSL (3 mg/kg). However, the levels that remain are within the range of background samples, as noted in [Section 8.2.1](#). The other contaminants in [Table 4](#) of Attachment F have concentrations that are less than their Industrial RSLs.

Total chromium results only exceed the hexavalent chromium Industrial RSL of 6.3 mg/kg, not the trivalent chromium Industrial RSL of 180,000 mg/kg.

## 8.5 Conclusions

The current Soil HHRA review found that most organic and inorganic constituents detected at the former Depot are present at levels that do not exceed current Industrial RSLs. Review of the screening risk estimates indicates the cumulative risks are within the acceptable risk range and HI values are less than or meet the acceptable limit of one in all FUs, except in FU-4 and FU-6 (residential scenario only). The primary contributor to the FU-4 risk estimates is dioxin, which will be evaluated in future activities at the MI (see below). In the UU/UE portion of FU-6, calculation of risk estimates using the Residential RSLs indicates exceedances of the acceptable limits primarily due to PCB Aroclor 1260, benzo(a)pyrene, dieldrin and arsenic. Therefore, with the exceptions noted below, it does not appear that a revised soils-only HHRA is

necessary in order to adequately assess potential incremental health risks and assure protectiveness of the remedy.

- Limited sampling was performed in the UU/UE portion of FU-6. A removal action was conducted in 1998 to excavate a total area of 103,000 square feet in the housing area with elevated dieldrin concentrations. Total chromium was detected in one sample location and the area will be sampled and analyzed for chromium speciation in future activities at the MI (see below). In addition, the 2000 MI RI indicates a potential for historic spills and PAH and pesticide contamination to be present in the non-UU/UE area of FU-6. Additional characterization of soil for other contaminants will be performed to address the uncertainty for risk in UU/UE area due to EPCs being calculated based on samples within and outside the UU/UE area, and the potential for PAH and pesticide contamination from historic spills outside the UU/UE area.
- All of the analytical results for lead in FU-2, FU-5 and FU-6 are less than the Industrial Soil RSL of 800 mg/kg. Certain analytical results in surface soil (0-2 ft) in FU-1, FU-3 and FU-4 are greater than 800 mg/kg: two results of 1,120 and 1,680 mg/kg exceed in FU-1, four results of 960, 2,230, 2,670 and 10,300 mg/kg exceed in FU-3 and three results of 878, 1,060 and 2,420 mg/kg exceed in FU-4. The location of the sample with a result of 10,300 mg/kg is near the excavation areas in FU-3, and it may have been excavated as part of the removal action. Additional sampling and analysis for lead will better characterize lead concentrations and identify areas requiring further remedial action to assure protectiveness in those FUs where lead has been detected above the RSL, i.e., FU 1, 3 & 4.
- Total chromium results exceed the hexavalent screening value (6.3 mg/kg) in numerous samples but do not exceed the value for trivalent chromium (180,000 mg/kg) at any samples. Total chromium concentrations are expected to consist mainly of trivalent chromium since it occurs naturally, while hexavalent chromium is most commonly produced by industrial processes; air emissions of chromium are also predominantly of trivalent chromium (USEPA, 2000). Speciation analysis should be considered to measure the actual ratio of trivalent to hexavalent chromium.
- Arsenic concentrations exceed their current industrial value in several locations. However, the concentrations are within the range of background concentrations identified for the site, state and eastern United States, as well as the range of cleanup levels used at Superfund sites across the country. Further investigation of arsenic in soil at the MI is not considered necessary.
- Screening levels for dioxins/furans were established after the MI RI was completed. The current status and continued enforcement of both the dioxin-related land use restrictions for the former Dip Vat area and the PCP-related restrictions in the 2005 MI NLUR are being reviewed in planning additional sampling and risk assessment of soils to assure protectiveness of the remedy. Other areas where dioxins/furans were detected but no LUCs were instituted (including shallow and deeper soils within a portion of FU3 and FU4, as well as other media) are also being reviewed to determine what additional work is needed to assure both human health and ecological risks are properly addressed. The

protocol provided in the *Tri-Service Environmental Risk Assessment Workgroup Questions/Answers on Dioxin* (TSERAWQ, 2013) is being used as guidance.

- These restricted areas are largely co-located, as PCP use is a likely source of the dioxins in soil. The MI LUCIP (CH2M HILL 2004b) references the MI NLUR; it does not mention the dioxin- or PCP-related land use restrictions.

## 9 Review of 2000 SLERAs

### 9.1 Overview and SLERA Methodology

#### 9.1.1 Overview

HDR has conducted a review of the SLERAs for FU1 through FU6 in the 2000 MI RI to determine if the conclusions are still valid and whether the SLERAs should be updated.

The approach to the 2000 SLERAs included assessment of ecological impacts from surface soil, surface water, and/or sediments; this review includes assessment of the methodology used in the 2000 SLERAs and a comparison of analytical data for COPCs to current ecological screening levels.

The 2000 MI RI noted that there was minimal to no ecological habitat throughout the MI; these conditions have not changed since that time.

#### 9.1.2 SLERA Methodology

The 2000 SLERAs were conducted in accordance with the *Ecological Risk Assessment Guidance for Superfund: Process for Designing and Conducting Ecological Risk Assessments* (USEPA 1997). The guidance includes eight general steps, of which Steps 1, 2, and 3 were performed in preparing the 2000 MI RI. These include:

1. Screening level problem formulation and toxicity evaluation;
2. Screening level exposure estimate and risk calculation; and
3. COPC refinement and problem formulation for baseline ERA (BERA)

The first two steps provide the means to complete a screening level, conservative assessment of which contaminants and exposure pathways require further evaluation and which do not. These steps use existing site data with minimal risk management input. Step 3a, COPC refinement, is performed to reevaluate the COPCs from Step 1 that were retained for further evaluation. COPCs retained based on very conservative exposure scenarios may be eliminated from further consideration, the remaining COPCs are carried forward to the BERA. Step 3b, problem formulation, focuses the scope and magnitude of the BERA.

The Step 1 screening level problem formulation, described in Section 7.8 of the 2000 MI RI, included development of a CSM for each FU to address the following:

- Environmental Setting and Contaminants at the Site: Identifies on- and off-site land uses, contaminants detected at the site, potential contaminant migration pathways, ecological habitats (e.g., wetlands, impoundments), observed or potentially occurring species, and identification of any protected species or critical habitats.
- Contaminant Fate and Transport: Identifies potential pathways for migration of site contaminants (e.g., surface water runoff). Detected contaminants in environmental

media are noted, as are the maximum detected concentrations to be used as ecological EPCs in the screening assessment;

- **Complete Exposure Pathways:** Evaluates potential ecological exposure pathways. For a pathway to be complete, a contaminant must travel from the source to an ecological receptor, via one or more exposure routes. It is noted in the RI that ecological habitats are minimal to nonexistent at the MI; a conservative approach was used so that potential ecological risks were not missed. More realistic exposure assumptions are considered in Step 3.
- **Assessment and Measurement Endpoints:** Develops assessment endpoints, expressions of the environmental values to be protected, based on the ecological exposure pathways considered potentially complete. The 2000 SLERAs included comparison of maximum EPCs to conservative screening level benchmarks.

The ecological CSMs for surface soil, surface water and sediment exposures were provided for each FU in [Figures 10-2, 14-2, 18-2, 22-2, 26-2 and 30-2](#) of the 2000 MI RI, respectively (Attachment G). The 2001 MI ROD provided a comprehensive CSM for human health and ecological exposure to groundwater and soil in [Figure 2-21](#) (Attachment G).

The Step 2 screening level risk estimate was performed using the HQ approach, with HQs being derived by dividing the EPCs by the screening ecotoxicity values. Using this approach, a HQ less than one indicates that the contaminant is unlikely to cause adverse effects; therefore these contaminants were not assessed further. Contaminants with an HQ greater than or equal to one are considered a potential ecological risk (with higher HQs indicating that the potential is increasing) and are carried forward to Step 3 of the BERA. Contaminants with no ecotoxicity screening criteria were also carried forward to assure all potential toxicity was considered.

Conservative thresholds for adverse ecological effects, i.e., screening ecotoxicity values, were used in the SLERAs. The sources for the ecotoxicity values used in the 2000 SLERAs are listed below. Also listed are the current criteria used by HDR for the SLERA review, taken from USEPA Region 4 *Ecological Risk Assessment Supplemental Guidance* (USEPA 2018b):

- **Soil**
  - o Draft Ecological Screening Levels for Soil from “Memorandum – Ecological Risk Assessment at Military Bases: Process Considerations, Timing of Activities, and Inclusion of Stakeholders” (USEPA 1998b); these values are presented in Table 7-14 of the 2000 MI RI.
  - o HDR’s current review of the surface soil data applies the USEPA Region 4 Soil Screening Values, updated in March 2018 (Table 3; USEPA 2018b).
- **Surface Water**
  - o Surface Water chronic values were taken from the USEPA Region 4 Supplemental Guidance to RAGS: Region 4 Bulletins, Freshwater Surface Water Screening Values for Hazardous Waste Sites (USEPA 1995b); these values are presented in Table 7-12 of the 2000 MI RI.

- o HDR's current review of the surface water data, documented below, applies the USEPA Region 4 Freshwater Chronic and Acute Screening Values, updated in March 2018 (Tables 1a and b; USEPA 2018b).
- Sediment
  - o Sediment screening values were taken from the USEPA Region 4 Supplemental Guidance to RAGS: Region 4 Bulletins, Sediment Screening Values for Hazardous Waste Sites (USEPA 1995c); these values are presented in Table 7-13 of the 2000 MI RI.
  - o HDR's current review of the sediment data, documented below, applies the USEPA Region 4 Freshwater Sediment Ecological Screening Values for Non-Narcotic and Narcotic Modes of Action, updated in March 2018 (Tables 2a and b; USEPA 2018b).

The maximum concentrations of all chemicals detected in surface water, sediment, or soil were used as the EPCs for estimating risk to fish, aquatic invertebrates and terrestrial organisms. Only potentially complete exposure pathways were addressed.

An assessment of the types and extent of uncertainty related to the risk evaluations was also performed. Professional judgment was used to assess the uncertainty associated with information taken from the literature, which was used in developing screening ecotoxicity values and other factors.

At the end of Step 2, a Scientific Management Decision Point (SMDP) was made about whether the information available is adequate to make a risk management decision. The three possible decisions at this point included:

- There is adequate information to conclude that ecological risks are negligible and thus there is no need for remediation on the basis of ecological risk;
- The information is not adequate to make a decision at this point, and the SLERA process will continue to Step 3 of the BERA; and
- The information indicates a potential for adverse ecological effects, and a BERA is warranted.

The Step 2 screening for each FU at the MI indicated there was adequate information and a potential for adverse ecological effects. The identified COPCs were carried forward through Step 3, the first step of the BERA.

Steps 3a and 3b refine the COPCs and problem formulation developed in the screening level assessment. The assumptions and site-specific information were reconsidered to refine the list of COPCs and to assess the scope and goals of a possible BERA. The revised assumptions and site-specific considerations used in the 2000 MI RI included:

- Use of arithmetic average contaminant concentrations, as well as maximum concentrations;
- Contaminant concentrations were compared to background;

- Frequency of detection was considered;
- Acute or lowest observed adverse effects level (LOAEL) ecotoxicity screening values were considered;
- Other literature sources of ecotoxicity screening values may be included where appropriate (e.g., if no ecotoxicity screening value was available in Step 2); and
- No state or federally listed or proposed endangered or threatened species were known to inhabit the area of FUs 1 through 6 (TDEC 1996; USFWS 1996).

The following additional considerations were used to calculate a range of HQs:

- Maximum versus chronic criteria/no observable adverse effects level (NOAEL);
- Maximum versus acute criteria/LOAEL;
- Average versus chronic criteria/NOAEL; and
- Average versus acute criteria/LOAEL.

The conservative ecological exposure pathways used in Step 2 were also reevaluated based on actual site conditions. If no constituents or exposure pathways of concern are identified as a result of the refinement process, a SMDP is developed indicating that ecological risks are negligible and there is no need for remediation on the basis of ecological risk. If issues remain following the refinement process, further evaluation should be completed.

The steps and assumptions from the 2000 MI RI described above are in accordance with applicable current guidance and serve as the basis for HDR's review.

## 9.2 SLERA Issues Considered in Current Review

### 9.2.1 Scientific Management Decision Points

The SMDPs in the 2000 MI RI were evaluated as to whether the conclusions reached at that time have changed and if so, the basis for that change. Note that there are not any new data for soil, sediment and surface water; therefore, the COPC concentrations used are the same for the 2000 SLERAs and the current review of potential ecological risks. Changes in ecotoxicity values and site conditions, particularly as they relate to the presence or absence of endangered species and/or suitable habitat and off-site transport of contaminants are also considered.

### 9.2.2 Endangered Species/Habitat

There were no state or federally listed or proposed endangered or threatened species known to inhabit the area of the site (TDEC 1996; USFWS 1996).

Review of current sources indicates there are 94 listed species believed to or known to occur in Tennessee (USFWS 2015). TDEC's Rare Species by County online database indicates that there are 32 rare species listed in Shelby County, Tennessee: two amphibians, nine birds, three fish, ten plants, one insect, two mammals, three mollusks and one reptile (TDEC 2016, 2017). The USFWS Environmental Conservation Online System for Shelby County indicates four listed

species are potentially present: bald eagle, least tern, Indiana bat and northern long-eared bat (USFWS 2015). No threatened or endangered species were identified at DDMT in the 2000 MI RI.

There are no on-site or near-site natural habitats that could support significant populations of terrestrial wildlife. The limited ecological habitat within the MI was considered to be highly disturbed and of poor quality in the RI and remains so today. Therefore, there are no complete ecological exposure pathways at DDMT.

### 9.2.3 Off-site Surface Water Transport

The potential impact to local watersheds was assessed in order to evaluate the potential for ecological impacts from the conveyance of runoff off-site. The surface drainage from each of the FUs is shown on [Figure G-1](#) in Attachment G.

HDR reviewed the Nonconnah Creek Watershed [Hydrologic Unit Code (HUC) 08010211] of the Mississippi River Basin Water Quality Management Plan (TDEC, 2002).

The water quality assessment for rivers and streams in the Nonconnah Creek Watershed indicates that while some portions of the watershed partially support its designated use, larger portions do not. The designated use includes the support of fish and aquatic life and the attainment of applicable ambient surface water quality standards. Streams in the watershed are impaired due to enrichment by organic matter and low dissolved oxygen levels, pathogens and other factors. Approximately 15 percent of the watershed is either forested or wetlands; residential development and agriculture are the dominant land uses.

There are seven documented Rare Plant and Animal Species and one rare snail species in the Nonconnah Creek Watershed listed in the management plan. The watershed is not considered as a significant resource based on its natural and scenic qualities or its value as a fishery. Based on the findings of the watershed assessment indicating a low resource value, any runoff from the MI is unlikely to have a significant impact on the ability of local surface water bodies to support wildlife and aquatic-dependent species or habitat. The potential transport of dioxin/furans warrants additional study in accordance with the Tri-Service *Environmental Risk Assessment Workgroup Questions/Answers on Dioxin* (TSERAWQ, 2013), as discussed in Sections 8.2.2.4 and 8.5.

## 9.3 SLERA Conclusions and Review of Current Conditions by FU

The following sections briefly summarize the SLERA and the finding of this review for each FU, including site description, media sampled, COPCs identified, SLERA conclusions, changes in site conditions since 2000, comparison of analytical results to current criteria, and the review conclusions.

### 9.3.1 FU1

#### 9.3.1.1 SLERA Summary

FU1 is fully developed with closely spaced warehouses. The landscaped strips between warehouses and roads/parking areas provide little ecological habitat for plants or animals. There are no on-site ponds, ditches or wetlands. Wildlife may include human-tolerant birds (e.g., sparrows, rock doves, grackles, mockingbirds) and small mammals (e.g., mice). This FU is expected to remain a light industrial area in the future.

Stormwater runoff generated within FU1 is conveyed via underground pipes to Lake Danielson or into a ditch below the lake's dam that drains to an unnamed tributary and Nonconnah Creek. Runoff in other portions of FU1 drains to Tarrant Branch, which also empties into Nonconnah Creek.

Only soil samples were collected in FU 1. Based on the Weight of Evidence presented in Table 10-10 of the 2000 MI RI, a few inorganic and several organic COPCs detected in soil have potential for adverse effects. These included selenium, dieldrin, TCE, Aroclor-1260 and several PAHs, for which HQs were at or above 1.0, and/or detected above background levels. Surface soil criteria for eight contaminants were not available for comparison, so HQs could not be determined; however, four (carbazole, carbon disulfide, methyl ethyl ketone and xylenes) were compared to available background concentrations. Those without criteria or background values (2-hexanone, acetone, bromomethane and petroleum hydrocarbons) were carried through as COPCs, as required by guidance.

The key consideration in the 2000 SLERA for FU1 was the lack of habitat and therefore, no complete ecological exposure pathways were identified.

#### 9.3.1.2 Current Review Conclusions

A comparison of the RI surface soil data within FU1 to current USEPA Region 4 ecological screening criteria, updated in March 2018, indicates the same constituents as identified in 2000 exceed their respective criterion, with the exception of TCE. Several PAHs (including benzo (a)pyrene); inorganics (e.g., arsenic, chromium, manganese, lead); and pesticides (e.g., DDT) also exceed criteria, as shown on [Table 1](#) in Attachment G.

Although several COPCs were identified as exceeding ecological criteria, the lack of complete ecological exposure pathways and the limited resource value of off-site water bodies that may receive runoff, site conditions indicate that current and future ecological impacts are negligible.

HDR's review of the 2018 ecotoxicity criteria, detected COPC concentrations and site conditions supports the general conclusions in the 2000 MI RI. Further review of FU1 soil analytical results is being performed to evaluate the potential for COPCs to be conveyed off-site via stormwater runoff. The review will be included in a QAPP being prepared for additional sampling and risk assessment, as discussed in [Section 9.4](#).

## 9.3.2 FU2

### 9.3.2.1 SLERA Summary

FU2 contains a golf course, several copses of mature trees and grassed areas; most of FU2 is grass covered, not paved. There is little ecological habitat for plants or animals due to regular maintenance of the golf course. Soil, sediment and surface water data were collected during the RI.

There are two surface water bodies, Golf Course Pond and Lake Danielson in FU2. Most runoff flows to a concrete-lined ditch below Lake Danielson or to the ditch below the Golf Course Pond. Both drain to unnamed tributaries of Nonconnah Creek.

Several sediment COPCs remained after Step 3 was completed in the 2000 MI RI (Table 14-17); the potential for adverse effects on the benthic community was determined to be minimal based on the low HQs. Bioaccumulation within the aquatic food chain was identified as potentially occurring in these ponds. In a separate study (Radian 1999) referenced in the RI, the ingestion of pesticides (detected in fish and amphibians) by piscivorous birds was determined unlikely to result in adverse effects. Therefore, the potential for adverse effects from sediment COPCs was considered negligible.

Refinement of surface soil and surface water COPCs (Tables 14-15 and 14-16 of the 2000 MI RI) indicated that, based on the weight of evidence and poor quality habitat, current and future ecological effects were negligible. No further assessment of ecological risk at FU2 was deemed to be warranted.

### 9.3.2.2 Current Review Conclusions

Comparison of the soil data against the current USEPA Region 4 ecological screening criteria, updated in March 2018, indicates exceedances in soil within FU2. PCE, bis(2-ethylhexyl)phthalate (BEHP), carbazole, fluoranthene, several pesticides (e.g., DDT) and inorganics (e.g., lead, manganese, zinc, arsenic and chromium) exceed current criteria as shown on [Table 1](#) in Attachment G.

No new sediment data have been collected and there are no numerical state sediment criteria; therefore, the existing data were compared to current USEPA Region 4 freshwater sediment ecological screening values for this review. That comparison indicates that for FU2, carbon tetrachloride, PAHs (including benzo(a)pyrene), pesticides (e.g., DDT), several types of furans and dioxins and inorganics (e.g., arsenic, barium, chromium, lead and zinc), were identified as being present at levels exceeding 2017 sediment criteria. Note that fewer constituents had screening levels available for comparison to detected concentrations at the time of the 2000 MI RI. These include several volatile organics, PAHs, furans and dioxins. The results of the current comparison are detailed in [Table 2](#) in Attachment G.

No new surface water data were collected; therefore, previously collected data from FU2 are compared to current USEPA Region 4 freshwater acute and chronic ecological screening

values. This comparison indicates that DDT, dieldrin, aluminum, copper, lead, selenium and zinc exceed their respective freshwater screening values as shown on [Table 3](#) in Attachment G.

HDR's review of the 2018 ecotoxicity criteria, detected COPC concentrations and site conditions (including the status of the Nonconnah Creek watershed as an ecological resource) support the general conclusions in the 2000 MI RI. Further review of FU2 soil, sediment and surface water analytical results is being performed to evaluate the potential for COPCs to be conveyed off-site via stormwater runoff. The review will be included in a QAPP being prepared for additional sampling and risk assessment, as discussed in [Section 9.4](#).

### 9.3.3 FU3

#### 9.3.3.1 SLERA Summary

FU3 contains two, long one-story buildings (970 and 972) and several smaller buildings surrounded by gravel and/or asphalt used for storage and equipment assembly. The majority of FU3 is owned by Barnhart Crane and Rigging and is used for their operations. A mowed utility corridor is present along the western boundary and a large undeveloped field is located in the eastern half of FU3. There is no suitable habitat for ecological receptors within this FU.

The 2000 MI RI describes stormwater in FU3 as being routed to underground pipes that lead to Tarrant Branch and eventually to Nonconnah Creek. No sediment or surface water samples were collected in this FU.

Several COPCs were identified in Step 3 of the 2000 MI RI (Table 18-14) as potentially causing adverse ecological effects; however, the lack of complete ecological exposure pathways at FU3 indicated that current and future ecological effects were negligible. No further assessment of ecological risks at FU3 was deemed to be warranted.

#### 9.3.3.2 Current Review Conclusions

A comparison of the concentrations of contaminants in surface soil to the current USEPA Region 4 ecological criteria, updated in March 2018, indicates that several PAHs (e.g., benzo(a)pyrene, chrysene), pesticides, dioxins/furans and inorganics (e.g., arsenic, barium, chromium and lead) exceed their respective criterion in soil.

Although several COPCs were identified as exceeding ecological criteria, the lack of complete ecological exposure pathways and the limited resource value of off-site water bodies that may receive stormwater runoff indicate that current and future ecological impacts are negligible. HDR's review of the 2018 ecotoxicity criteria, detected COPC concentrations and site conditions supports the general conclusion in the 2000 MI RI. Further review of FU3 soil analytical results is being performed to evaluate the potential for COPCs to be conveyed off-site via stormwater runoff. The review will be included in a QAPP being prepared for additional sampling and risk assessment, as discussed in [Section 9.4](#).

### 9.3.4 FU4

#### 9.3.4.1 SLERA Summary

FU4 includes the northwest quadrant of the MI and a large, undeveloped section along the northern boundary of the MI. The northwest quadrant contains three large one-story buildings (835, 925 and 949) and a few smaller buildings surrounded by gravel and/or asphalt used for storage and equipment assembly; the majority of this area is owned by Barnhart Crane and Rigging and is used for their operations. A mowed utility corridor is also present along the western boundary as in FU3. The section along the northern boundary is largely grassed and has a stormwater detention basin in the eastern section; there is one large building (210) and an adjacent parking area in the northeast corner of the MI. There is no suitable habitat for ecological receptors within this FU.

The 2000 MI RI notes that stormwater runoff from FU4 flows to either concrete-lined ditches or underground drainage pipes that lead to Cane Creek, which eventually flows to Nonconnah Creek.

Several COPCs were identified as exceeding ecological criteria in surface soil and sediment in the 2000 MI RI Step 3 (Tables 22-16 and 22-18). However, none of the COPCs identified in surface water (Table 22-17 of 2000 MI RI) indicated adverse ecological effects. The 2000 SLERA for FU4 noted that the lack of complete ecological exposure pathways at FU4 indicates that current and future ecological effects are negligible. No further assessment of ecological risk associated with contaminants at FU4 was deemed to be warranted.

#### 9.3.4.2 Current Review Conclusions

HDR's review of current USEPA Region 4 ecotoxicity criteria, updated in March 2018, and detected COPC concentrations in soil within FU4 indicates bromomethane, several PAHs (e.g., benzo(a)pyrene), pesticides (e.g., dieldrin), Aroclor 1260, dioxins/furans and inorganics (e.g., arsenic, total chromium) exceed their respective criterion as shown in [Table 1](#) of Attachment G.

Comparing the earlier sediment analytical results for FU4 to current USEPA Region 4 screening values indicates carbon tetrachloride, methylene chloride, 2 methyl-naphthalene, several PAHs (e.g., benzo(a)pyrene), DDT and other pesticides, certain dioxins/furans and several inorganics (e.g., arsenic, barium, chromium, lead, zinc) exceed their respective screening values, as shown in [Table 2](#) in Attachment G.

Comparison of maximum detected concentrations in surface water from previous sampling against current USEPA Region 4 screening values indicates that BEHP, dieldrin, DDT, dioxins/furans and inorganics (i.e., aluminum, copper, iron, lead and silver) exceed freshwater screening values as shown in [Table 3](#) in Attachment G; there were no dioxin screening values available at the time of the original analysis.

Although several COPCs in soil, sediment and surface water were identified as exceeding current ecological criteria, the lack of complete ecological exposure pathways and the limited resource value of off-site water bodies that may receive stormwater runoff indicate that current

and future ecological impacts are negligible, supporting the general conclusion in the 2000 MI RI. Further review of FU4 soil, sediment and surface water analytical results is being performed to evaluate the potential for COPCs to be conveyed off-site via stormwater runoff. The review will be included in a QAPP being prepared for additional sampling and risk assessment, as discussed in [Section 9.4](#).

### 9.3.5 FU5

#### 9.3.5.1 SLERA Summary

FU5 contains the newer warehouses in the south-central MI. The buildings are surrounded by paved streets and parking with grassed strips and some landscaped areas.

Several soil COPCs (Table 26-11 of 2000 MI RI) were identified as potentially causing adverse ecological effects. Due to the lack of complete ecological exposure pathways at FU5, the 2000 SLERA concluded that current and future ecological impacts were negligible; no further assessment was deemed to be warranted.

The 2000 MI RI notes that stormwater runoff from FU5 is transported via underground pipes to an unnamed tributary or to Tarrant Branch that eventually discharge to Nonconnah Creek.

#### 9.3.5.2 Current Review Conclusions

A review of current USEPA Region 4 ecotoxicity criteria, updated in March 2018, against surface soil data indicates that several PAHs (e.g., benzo(a)pyrene), pesticides, dibenzofuran and inorganics exceed their respective criterion ([Table 1](#) in Attachment G).

Although several COPCs in soil were identified as exceeding current ecological criteria, the lack of complete ecological exposure pathways and the limited resource value of off-site water bodies that may receive stormwater runoff indicate that current and future ecological impacts are negligible, supporting the general conclusion in the 2000 MI RI. Further review of FU5 soil analytical results is being performed to evaluate the potential for COPCs to be conveyed off-site via stormwater runoff. The review will be included in a QAPP being prepared for additional sampling and risk assessment, as discussed in [Section 9.4](#).

### 9.3.6 FU6

#### 9.3.6.1 SLERA Summary

FU6 contains the main administrative building (now used by Barnhart Crane), the new police precinct buildings, small office and maintenance buildings, and residential buildings in the southeastern strip. There are large paved parking areas adjacent to the buildings with small grassed areas and a few plantings. The residential area is grassed and has large trees. Stormwater runoff generated within this FU ultimately flows off-site to an unnamed tributary of Nonconnah Creek.

Several soil COPCs were identified in Step 3 (Table 30-13 of 2000 MI RI) as potentially causing adverse ecological effects. The lack of complete ecological exposure pathways in this area

indicated that ecological effects were negligible and no further assessment of ecological risk was recommended.

#### 9.3.6.2 Current Review Conclusions

HDR's review of contaminant concentrations in surface soil compared to current USEPA Region 4 criteria, updated in March 2018, indicates the maximum concentrations of bromomethane, several PAHs (e.g., benzo(a)pyrene), Aroclor 1260, pesticides and several inorganics (e.g., arsenic, lead, manganese) exceed criteria as shown on [Table 1](#) in Attachment G.

Although several COPCs in soil were identified as exceeding current ecological criteria, the lack of complete ecological exposure pathways and the limited resource value of off-site water bodies that may receive stormwater runoff indicate that current and future ecological impacts are negligible, supporting the general conclusion in the 2000 MI RI. Further review of FU6 soil analytical results is being performed to evaluate the potential for COPCs to be conveyed off-site via stormwater runoff. The review will be included in a QAPP being prepared for additional sampling and risk assessment, as discussed in [Section 9.4](#).

#### 9.3.7 Dioxins/Furans

As noted in [Section 8.2.2](#), neither human health nor ecological soil screening levels for dioxins/furans were available for the 2000 MI RI. As part of the SLERA review, the maximum detected dioxin and furan congener-specific concentrations and the calculated TCDD equivalent surface soil concentrations ([Table 4a](#) in Attachment G) were compared to current USEPA ecological soil screening levels. The data indicates exceedances for dibenzofuran in FU1, FU3, FU4 and FU5; and several dioxin/furan congeners in FU3 and FU4, described in further detail below.

Background values for dioxin and furan concentrations ([Table 3-10](#) in Attachment F) are less than the maximum detected concentrations in FU2 and FU4 for surface soil, sediment and surface water (Attachment G, [Tables 4a to 4c](#)). The background values for TCDD equivalents are 0.010 µg/kg in surface soil, 0.009 µg/kg in sediment and 0.018 ng/L in surface water.

The soil background dioxin and furan concentrations in FU3 are similar to maximum detected concentrations on a congener-specific basis. For example, the octachlorodibenzo-p-dioxin background concentration is 9.72 µg/kg compared to the maximum concentration of 10.25 µg/kg. In FU4, the TCDD Equivalent maximum detected concentrations of 0.083 µg/kg in surface soil, 0.129 µg/kg in sediment and 0.028 ng/L in surface water all exceed background values.

Dioxin/furan concentrations in sediment samples from FU2 and FU4 have numerous screening level exceedances, as shown on [Table 4b](#) in Attachment G. For example, the TCDD equivalent maximum detected concentrations are two orders of magnitude higher than the ecological screening value. The surface water TCDD equivalent maximum detected concentration is significantly higher than the chronic EPA Region 4 ecological freshwater screening value, as shown on [Table 4c](#) in Attachment G.

As noted in [Section 8.2.2.4](#), the *Tri-Service Environmental Risk Assessment Workgroup Questions/Answers on Dioxin* (TSERAWQ, 2013) recommends environmental investigations focus on the potential for direct-contact pathways for both human and ecological receptors. In addition, remediation of these contaminants should address both human health and ecological risks. Ecological impacts will be considered in determining whether further evaluation should be performed to assure protectiveness of the remedy for DDMT and soil, sediment and surface water will be included in that evaluation,.

## 9.4 Conclusions

As noted above, the SLERAs completed in 2000 included an evaluation of ecological impacts from surface soil, surface water, and/or sediments. This review is based solely on a comparison of historic data to current ecological screening levels, updated in March 2018. The current review indicates that the levels of certain COCs in environmental media exceed their respective screening levels.

In 2000, it was noted that there is minimal to no suitable ecological habitat throughout the MI; these conditions have not changed and there are no apparent complete ecological pathways of exposure on-site. Therefore, on-site ecological risk is considered minimal.

Comparison of soil data from the MI RI to current USEPA Region 4 soil ecological screening values (USEPA 2018b) indicates that certain contaminants, including bromomethane, PCE, several PAHs (e.g., benzo(a)pyrene), pesticides (e.g., DDT, dieldrin), Aroclor 1260, dioxins/furans and inorganics were present at levels exceeding soil criteria, as shown on [Table 1](#) in Attachment G.

Comparison of sediment data from the MI RI to current USEPA Region 4 freshwater sediment ecological screening values (USEPA 2018b) indicates that contaminants, including carbon tetrachloride, methylene chloride, PAHs, pesticides, dioxins/furans and metals were present at levels exceeding sediment criteria, as shown on [Table 2](#) in Attachment G.

Surface water data from the MI RI were compared to current USEPA Region 4 freshwater acute and chronic ecological screening values (USEPA 2018b). Dieldrin, DDT, dioxins/furans, aluminum, copper, iron, lead, silver and zinc exceed their screening values, as shown on [Table 3](#) in Attachment G.

HDR's review of ecotoxicity criteria, detected COPC concentrations and site conditions (including the status of the Nonconnah Creek watershed as having limited ecological resource value) largely supports the conclusion in the 2000 MI RI that there is negligible ecological risk from stormwater runoff or other potential ecological exposure pathways emanating from DDMT.

Because there is potential for COPCs to be conveyed off-site via stormwater runoff, the detection of dioxin/furans in on-site soil, as well as in surface water and sediment in local streams warrants additional study in accordance with the *Tri-Service Environmental Risk Assessment Workgroup Questions/Answers on Dioxin* (TSERAWQ, 2013). The results of this study, including review of the existing analytical results from FU1 to FU6, will be included in a QAPP being prepared for additional sampling and risk assessment.

## 10 HHERA Conclusions and Recommendations

### 10.1 Groundwater HHRA Update

The results of the Groundwater HHRA update indicate that there is potential for receptors to experience adverse health effects from exposure to contaminated on-site groundwater.

These are currently being prevented by the existing land use restrictions at the MI, which are:

- No residential land use or other child-occupied facilities, including daycare on the MI; and
- No production/consumptive use of groundwater or drilling groundwater wells (does not apply to wells installed as part of the CERCLA action) on the MI.

As long as these restrictions are maintained, the exposure pathways related to the contaminated groundwater are not complete, with the possible exception of vapor intrusion. A work plan has been prepared for soil gas sampling, which is to be performed to better estimate human health risk via vapor intrusion. Sampling will be conducted in 2018.

### 10.2 Soil HHRA Review

The current Soil HHRA review found that most organic and inorganic constituents detected at the former Depot are present at levels that do not exceed current Industrial RSLs. Therefore, with certain exceptions, it does not appear that a revised soils-only HHRA is necessary in order to adequately assess potential incremental health risks and assure protectiveness of the remedy.

Additional risk assessment required to assure protectiveness of the remedy:

- The Soil HHRA review determined that additional soil sampling may be necessary on the MI.
- Additional sampling for chromium speciation analysis to evaluate the potential risks based on detection of total chromium at DDMT, as hexavalent chromium is much more toxic than the trivalent form.
- Review the current status and continued enforcement of both the dioxin-related land use restrictions for the former Dip Vat area and the PCP-related restrictions in the 2005 MI NLUR to evaluate the need for further sampling and risk assessment. The institutional controls, as enforced, in conjunction with the results of the HHRA and SLERA review should be considered in determining the need for remedial action in these areas.

### 10.3 SLERA Review

The findings of the current SLERA review indicate that concentrations of certain COCs in environmental media exceed their respective ecological screening levels. In 2000, it was noted

that there is minimal to no suitable ecological habitat throughout the MI; these conditions have not changed and there are no apparent complete ecological pathways of exposure on-site. Therefore, on-site ecological risk is considered minimal.

As noted, the detection of dioxin/furans in on-site soils, as well as in local surface water and sediment warrants additional study. The protocol for risk assessment provided in the *Tri-Service Environmental Risk Assessment Workgroup Questions/Answers on Dioxin* (TSERAWQ, 2013) will be used as guidance for further evaluation of ecological risk to determine protectiveness of the remedy in areas where detected concentrations of dioxin/furan contaminants exceed screening values and may or may not have impacted sediment and surface water.

## 10.4 Detection Limits for Additional Sampling

Based on the additional sampling recommended above and for the vapor intrusion study, proposed laboratory detection limits were compared to the screening levels applied in the risk assessments to check whether or not constituents can be detected at or below the screening levels. Current laboratory methods may be unable to achieve these risk-based screening levels.

Groundwater detection limits were compiled from the April 2017 LTM Summary Report (HDR 2017b) and the 2011 QAPP (HDR 2011) and the DDMT QAPP (HDR 2018) and presented in [Table 10-1](#). If more than one detection limit was identified, the lowest value was chosen. Comparison of the detection limits to the HHRA screening levels indicates all of the detection limits are less than the USEPA MCL (2017, 2019b) while approximately half of the COPCs have detection limits that are greater than the USEPA Tapwater RSLs (2019b).

**Table 10-1 Detection Limits for HHRA Groundwater COPCs**

| COPC                      | Method Detection Limit | Reporting Limit | HHRA Screening Levels |                           |           |
|---------------------------|------------------------|-----------------|-----------------------|---------------------------|-----------|
|                           |                        |                 | MCL                   | RSL Tapwater (1E-06, 0.1) | RSL Basis |
| 1,1,2,2-Tetrachloroethane | 0.2                    | 0.5             | NC                    | 0.076                     | c         |
| 1,1-Dichloroethene        | 0.5                    | 1               | 7                     | 28                        | n         |
| 1,2,3-Trichloropropane    | 0.5                    | 1               | NC                    | 0.00075                   | c*        |
| 1,2,4-Trimethylbenzene    | 0.25                   | 1               | NC                    | 5.6                       | n         |
| 1,2-Dichloroethane        | 0.25                   | 0.5             | 5                     | 0.17                      | c**       |
| 1,2-Dichloropropane       | 0.2                    | 1               | 5                     | 0.82                      | n         |
| Acetone                   | 2.5                    | 10              | NC                    | 1400                      | n         |
| Carbon tetrachloride      | 0.25                   | 1               | 5                     | 0.46                      | c*        |
| Chloroform                | 0.125                  | 0.3             | 80                    | 0.22                      | c*        |
| cis-1,2-Dichloroethylene  | 0.25                   | 1               | 70                    | 3.6                       | n         |
| Methyl Ethyl Ketone       | 2.5                    | 10              | NC                    | 560                       | n         |
| Methyl tert-butyl ether   | 0.5                    | 5               | NC                    | 14                        | c*        |

| COPC               | Method Detection Limit | Reporting Limit | HHRA Screening Levels |                           |           |
|--------------------|------------------------|-----------------|-----------------------|---------------------------|-----------|
|                    |                        |                 | MCL                   | RSL Tapwater (1E-06, 0.1) | RSL Basis |
| Methylene chloride | 0.25                   | 1               | 5                     | 11                        | n         |
| Tetrachloroethene  | 0.25                   | 1               | 5                     | 4.1                       | n         |
| Toluene            | 0.25                   | 1               | 1000                  | 110                       | n         |
| Trichloroethylene  | 0.25                   | <b>1</b>        | 5                     | 0.28                      | n         |
| Vinyl chloride     | <b>0.25</b>            | <b>1</b>        | 2                     | 0.019                     | c         |

**Notes:** All values are presented in units of µg/L. Exceedances of screening levels are **bolded**.  
**Abbreviations:** NC = no criterion; \* = non-cancer RSL < 100 times cancer RSL; \*\* = non-cancer RSL < 10 times cancer RSL; c = cancer; n = non-cancer

Soil detection limits for chromium, lead and TCDD were obtained from Microbac Laboratories. See [Table 10-2](#).

**Table 10-2 Detection Limits for Soil COPCs**

| Analyte                   | Method Detection Limit | Reporting Limit | HHRA/SLERA Screening Levels                    |                                  |           |
|---------------------------|------------------------|-----------------|------------------------------------------------|----------------------------------|-----------|
|                           |                        |                 | USEPA Region 4 Ecological Soil Screening Level | RSL Industrial Soil (1E-06, 0.1) | RSL Basis |
| Chromium, Total           | 0.5                    | 1               | 23                                             | NC                               |           |
| Chromium, Trivalent (3+)  | 0.05                   | 1               | 26                                             | 180000                           | nm        |
| Chromium, Hexavalent (6+) | 1                      | 2               | 0.34                                           | 6.3                              | c*        |

| TCDD (TEQ)                | 5.3E-06                | 3.3E-06         | 3.15E-06                                       | 2.2E-05                          | c**       |

**Notes:** All values are presented in units of mg/kg. Exceedances of screening levels are **bolded**.  
**Abbreviations:** NC = no criterion; \* = non-cancer RSL < 100 times cancer RSL; \*\* = non-cancer RSL < 10 times cancer RSL; c = cancer; n = non-cancer; m = concentration may exceed ceiling limit, see RSL User's Guide; L = see RSL User's Guide on lead

Soil gas detection limits for were compiled in the October 2017 MI VI Soil Gas Sampling QAPP and are presented in [Table 10-3](#). None of the detection limits are greater than the current default EPA Soil Gas VISLs for a Commercial scenario (USEPA 2018d).

**Table 10-3 Detection Limits for Soil Gas COPCs**

| Analyte                                                                                                                                                                                                                                  | Method Detection Limit | Reporting Limit | HHRA Screening Levels                 |

## Unit Boundaries

Main Installation  
Defense Depot  
Memphis, Tennessee

Operable Units (OU-#)

-  Functional Unit Boundary (FU-#)  
 Area Available for Unrestricted Use  
 Buildings 490 - DDMT Assigned Number  
 Roads

A horizontal number line is shown with tick marks at 0, 500, and 1,000. The word "Feet" is written below the line. A white rectangular segment is highlighted between the 250 and 500 marks, representing the distance from the end of the first segment to the end of the second segment.

NOTES

- Pathway assumed to be complete.
- \* Pathway assumed to be potentially insignificant.
- (a) Only groundwater exposures are evaluated in this HHRA update.
- (b) Assessed via EPA Vapor Intrusion Screening Level calculator.

| Current/Future        | Releases from on-site and off-site sources | On-Site Worker         | Adult        | Groundwater                    | Tapwater       | Ingestion      | Quantitative          | Contamination is present in the Fluvial and Intermediate/Upper Claiborne aquifers and there is potential for contamination to migrate to the deeper Memphis aquifer, which serves as a current source of drinking water. Ingestion and dermal contact with tapwater from on-Site sinks will be evaluated for a current/future worker, assuming no controls are in place to prohibit exposure to groundwater. Inhalation of contaminants via drinking water was considered to be insignificant. Inhalation via vapor intrusion is evaluated using groundwater-derived air concentrations with the USEPA Vapor Intrusion Screening Level (VISL) calculator. |
|                       |                                            |                        |              |                                |                | Dermal         |                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                       |                                            |                        |              |                                |                | Inhalation     | None                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                       |                                            |                        |              |                                | Indoor Air     | Inhalation     | Quantitative          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Future                |                                            | Off-Site Resident      | Adult        | Groundwater                    | Tapwater       | Ingestion      | Quantitative          | Institutional controls currently prohibit the installation of wells on-Site. There is potential for contamination to migrate to the Memphis aquifer; therefore, a future resident's exposure to groundwater via the ingestion, dermal and inhalation (during showering) pathways are quantitatively evaluated. Exposure to indoor air contaminants via vapor intrusion is evaluated using the USEPA VISL calculator.                                                                                                                                                                                                                                      |
|                       |                                            |                        |              |                                |                | Dermal         |                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

**Notes:**  
(1) The maximum detected concentrations for site-wide groundwater are used for the COPC screening. Groundwater data that do not meet the requirements in the USEPA memorandum titled *Determining Groundwater Exposure Point Concentrations, Supplemental Guidance* were not excluded from this screening, e.g., samples collected from piezometers (USEPA 2014).  
(2) Federal Maximum Contaminant Levels (MCLs) taken from USEPA Regional Screening Level (RSL) tables.  
(3) USEPA RSLs at a target risk of 1E-06 and target hazard quotient of 0.1.  
Only unfiltered (total) groundwater data is used for COPC screening.  
The COPC screening applies the minimum of the Federal MCLs and USEPA Tapwater RSLs.  
The COPC screening applies the criteria for xylenes (total) to its isomers.

|                                                                                                                                                                                                                                                 |                                                                                                                                                                                                                                                                                          |                                                                                              |                                                                                                                                                                                      |

| VOC               | cis-1,2-Dichloroethylene         | 156-59-2  | Yes             | Yes                                    | No              |
| VOC               | Methyl Ethyl Ketone (2-butanone) | 78-93-3   | Yes             | Yes                                    | No              |
| VOC               | Methyl tert-butyl ether          | 1634-04-4 | Yes             | No                                     | No              |
| VOC               | Methylene chloride               | 75-09-2   | Yes             | No                                     | No              |
| VOC               | Tetrachloroethylene              | 127-18-4  | Yes             | Yes                                    | Yes             |
| VOC               | Toluene                          | 108-88-3  | Yes             | No                                     | No              |
| VOC               | Trichloroethylene                | 79-01-6   | Yes             | Yes                                    | Yes             |
| VOC               | Vinyl chloride                   | 75-01-4   | Yes             | Yes                                    | No              |

**Note:**

The COPC list consists of constituents that are identified as a COPC in at least one aquifer. COPCs are identified with a "Yes" and shaded.

**Abbreviations:**

VOC -- Volatile organic compound

#### Notes:

These EPCs for groundwater will be used in the resident and worker scenarios. Only unfiltered (total) groundwater data are evaluated.  
The exposure point concentration (EPC) is the 95% upper confidence limit (UCL) of the arithmetic mean. When the UCL is greater than the maximum detected concentration or ProUCL did not calculate an UCL, the maximum detected concentration is chosen.  
The most appropriate UCL is chosen from those ProUCL suggests based on the distribution of the dataset and ProUCL guidance. ProUCL outputs are provided in Attachment B.  
For instances where ProUCL provided an output, but did not provide a suggested UCL, HDR calculated a non-parametric 95% UCL around the median or 50% percentile in accordance with the 2009 USEPA Unified Guidance Section 21.2. See Attachment B.

#### Abbreviations:

COPC -- Constituent of potential concern  
EPC -- Exposure point concentration  
Qual -- Qualifier  
NA -- Not analyzed or applicable  
ND -- Not detected  
UCL -- 95% Upper confidence limit

#### ProUCL Notes and Warnings:

b One or more recommended UCL not available.  
d Data set has only 1 Distinct Detected Values.  
e Data set has only 2 Detected Values.  
f Data set has only 3 Detected Values.  
g The data set was not processed.  
k The 95% KM Approximate Gamma UCL was chosen as the GROS UCL may yield incorrect UCLs when the data data set has greater than 50% nondetects.

**Notes:**

These EPCs for groundwater will be used in the resident and worker scenarios. Only unfiltered (total) groundwater data are evaluated.  
The exposure point concentration (EPC) is the 95% upper confidence limit (UCL) of the arithmetic mean. When the UCL is greater than the maximum detected concentration or ProUCL did not calculate an UCL, the maximum detected concentration is chosen.  
The most appropriate UCL is chosen from those ProUCL suggests based on the distribution of the dataset and ProUCL guidance. ProUCL outputs are provided in Attachment B.

**Abbreviations:**

COPC -- Constituent of potential concern  
EPC -- Exposure point concentration  
Qual -- Qualifier  
NA -- Not analyzed or applicable  
ND -- Not detected  
UCL -- 95% Upper confidence limit

**ProUCL Notes and Warnings:**

- d Data set has only 1 Distinct Detected Values.
- g The data set was not processed.
- I The 95% KM (t) UCL was chosen as it is more appropriate than the 95% KM (BCA) UCL and KM H-UCL.

#### Notes:

Intake equations are derived from USEPA's RSL equations and also taken from USEPA's Risk Assessment Guidance for Superfund (RAGS).  
The skin surface area available for contact is the weighted average of mean values for males and females combined for total surface area, which includes the head, trunk, arms, hands, legs and feet (USEPA 2014).

#### Abbreviations:

Adj -- Adjusted to include both adult and child exposure factors  
DAD -- Dermally absorbed dose  
EC -- Exposure concentration  
EPC -- Exposure point concentration  
RSL -- USEPA Regional Screening Level  
TCE -- Trichloroethylene  
USEPA -- United States Environmental Protection Agency  
VC -- Vinyl chloride

**Note:**  
(1) The EPC is the lower of the 95% upper confidence limit and maximum detected concentration. See Table 3s.  
The dermal parameters were taken from the chemical parameter table of the USEPA June 2017 RSL tables and RAGS Part E.

**Abbreviations:**  
CF1 -- Conversion Factor 1 (0.001 mg/ug)  
CF2 -- Conversion Factor 2 (0.001 L/cm<sup>3</sup>)  
C<sub>w</sub> -- Groundwater or surface water concentration  
VOC -- Volatile organic compound

**Note:**  
The oral RfDs are taken from the USEPA Regional Screening Levels (RSLs) table, which gathers toxicity reference values from multiple sources using an established hierarchy.  
The absorbed RfD for dermal is calculated by the following equation: RfD-oral x GIABS.  
USEPA recommends that the oral RfD should not be adjusted to estimate the absorbed dose for compounds when the absorption efficiency is greater than 50%.

**Abbreviations:**  
GIABS -- Gastrointestinal absorption factor  
NA -- Not available  
RfD -- Reference dose  
RSLs -- EPA Regional Screening Levels  
VOC -- Volatile organic compound

**Note:**

The oral SFs are taken from the USEPA Regional Screening Levels (RSLs) table, which gathers toxicity reference values from multiple sources using an established hierarchy.

The absorbed SFd for dermal is calculated by the following equation: SF-oral / GIABS.

USEPA recommends that the oral SF should not be adjusted to estimate the absorbed dose for compounds when the absorption efficiency is greater than 50%.

**Abbreviations:**

GIABS -- Gastrointestinal absorption factor

NA -- Not available

RSLs -- EPA Regional Screening Levels

SFd -- Dermal slope factor

SFo -- Oral cancer slope factor

VOC -- Volatile organic compound

**Note:**

The IURs are taken from the USEPA Regional Screening Levels (RSLs) table, which gathers toxicity reference values from multiple sources using an established hierarchy.

**Abbreviation:**

IUR -- Inhalation unit risk

NA -- Not available

RSLs -- EPA Regional Screening Levels

VOC -- Volatile organic compound

#### Notes:

The exposure point concentration (EPC) is the 95% upper confidence limit (UCL), except when the UCL was greater than the maximum detected concentration or ProUCL did not calculate an UCL.

The constituent of potential concern (COPC) list is based on exceedances from screening of maximum detected concentrations against risk-based criteria in the Table 2"s.

The single-chemical cancer risks incorporate the one hit equation if cancer risks are > 0.01, per RAGS Part A Chapter 8: Risk = 1 - exp(-Dose x SF). For the risks presented here, the one-hit equation is not needed.

The DAvent values for dermal exposure to groundwater are calculated in Table 4.Supp.3.

#### Abbreviations:

COPC -- Constituent of potential concern

CSF -- Oral cancer slope factor

EPC -- Exposure point concentration

IUR - Inhalation unit risk

RfC -- Inhalation reference concentration

RfD -- Oral reference dose

**Notes:**  
The exposure point concentration (EPC) is the 95% upper confidence limit (UCL), except when the UCL was greater than the maximum detected concentration or ProUCL did not calculate an UCL.  
The constituent of potential concern (COPC) list is based on exceedances from screening of maximum detected concentrations against risk-based criteria in the Table 2s.  
The single-chemical cancer risks incorporate the one hit equation if cancer risks are > 0.01, per RAGs Part A Chapter 8: Risk = 1 - exp(-Dose x SF). For the risks presented here, the one-hit equation is not needed.  
The age-adjustments for a resident's cancer risk are calculated in Table 4.Supp.1.  
The exposure intakes for MMOA chemicals (e.g., chromium) are adjusted for age are calculated in Tables 4.Supp.2.

**Abbreviations:**  
COPC -- Constituent of potential concern  
CSF -- Oral cancer slope factor  
EPC -- Exposure point concentration  
IUR - Inhalation unit risk  
RfC -- Inhalation reference concentration  
RfD -- Oral or dermal reference dose  
UCL -- Upper confidence limit

TABLE 7.2A - INTERMEDIATE AQUIFER  
CALCULATION OF COPC CANCER RISKS AND NONCANCER HAZARDS FOR A WORKER  
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

Scenario Timeframe: Future  
Receptor Population: Worker  
Receptor Age: Adult

**Notes:**  
The exposure point concentration (EPC) is the 95% upper confidence limit (UCL), except when the UCL was greater than the maximum detected concentration or ProUCL did not calculate an UCL.  
The constituent of potential concern (COPC) list is based on exceedances from screening of maximum detected concentrations against risk-based criteria in the Table 2s.  
The single-chemical cancer risks incorporate the one hit equation if cancer risks are > 0.01, per RAGs Part A Chapter 8: Risk = 1 - exp(-Dose x SF). For the risks presented here, the one-hit equation is not needed.  
The age-adjustments for a resident's cancer risk are calculated in Table 4.Supp.1.  
The exposure intakes for MMOA chemicals (e.g., chromium) are adjusted for age are calculated in Tables 4.Supp.2.

**Abbreviations:**  
COPC -- Constituent of potential concern  
CSF -- Oral cancer slope factor  
EPC -- Exposure point concentration  
IUR - Inhalation unit risk  
RfC -- Inhalation reference concentration  
RfD -- Oral or dermal reference dose  
UCL -- Upper confidence limit

**Notes:**  
The exposure point concentration (EPC) is the 95% upper confidence limit (UCL), except when the UCL was greater than the maximum detected concentration or ProUCL did not calculate an UCL.  
The constituent of potential concern (COPC) list is based on exceedances from screening of maximum detected concentrations against risk-based criteria in the Table 2"s".  
The single-chemical cancer risks incorporate the one hit equation if cancer risks are > 0.01, per RAGs Part A Chapter 8: Risk = 1 - exp(-Dose x SF). For the risks presented here, the one-hit equation is not needed.  
The DAvent values for dermal exposure to groundwater are calculated in Table 4.Supp.3.

**Abbreviations:**  
COPC -- Constituent of potential concern  
CSF -- Oral cancer slope factor  
EPC -- Exposure point concentration  
IUR -- Inhalation unit risk  
RfC -- Inhalation reference concentration  
RfD -- Oral reference dose

|-------------|----------------------|------------------------------------------------------------------------------------------------------------------------|
| Equation 1: | C <sub>a</sub> =     | ((C <sub>a-max</sub> /2) * t <sub>1</sub> + C <sub>a-max</sub> * t <sub>2</sub> ) / (t <sub>1</sub> + t <sub>2</sub> ) |
| Equation 2: | C <sub>a-max</sub> = | (C <sub>w</sub> * f * F <sub>w</sub> * t <sub>1</sub> ) / V <sub>a</sub>                                               |

**Note:**

(1) The EPC is the lower of the 95% UCL and maximum detected concentration - see Table 3s.

The most conservative value of the ranges for each exposure parameter, as presented in Schaum et al 1994, is applied for the calculations. The shower model air chemical concentrations are calculated for only VOCs.

Total exposure times for are 0.71 hr for an adult and 0.54 hr for a child (0-6 years). Professional judgement is used to split up the time spent in the shower versus in the bathroom after shower. An adult is assumed to spend approximately 15 minutes showering followed by 28 minutes in the bathroom, for a total of 43 minutes (0.71 hr). A child is assumed to spend approximately 20 minutes bathing followed by 13 minutes in the bathroom for a total of 32 minutes (0.54 hr).

**Abbreviation:**

CW -- Groundwater water concentration

EPC -- Exposure point concentration

VOC -- Volatile organic compound

Total exposure times for are 0.71 hr for an adult and 0.54 hr for a child (0-6 years). Professional judgement is used to split up the time spent in the shower versus in the bathroom after shower. An adult is assumed to spend approximately 15 minutes showering followed by 28 minutes in the bathroom, for a total of 43 minutes (0.71 hr). A child is assumed to spend approximately 20 minutes bathing followed by 13 minutes in the bathroom for a total of 32 minutes (0.54 hr).

**Abbreviation:**

CW -- Groundwater water concentration

EPC -- Exposure point concentration

VOC -- Volatile organic compound

Notes:  
The exposure point concentration (EPC) is the 95% upper confidence limit (UCL), except when the UCL was greater than the maximum detected concentration or ProUCL did not calculate an UCL.  
The constituent of potential concern (COPC) list is based on exceedances from screening of maximum detected concentrations against risk-based criteria in the Table 2s.  
The single-chemical cancer risks incorporate the one hit equation if cancer risks are > 0.01, per RAGs Part A Chapter 8: Risk = 1 - exp(-Dose x SF). For the risks presented here, the one-hit equation is not needed.  
The age-adjustments for a resident's cancer risk are calculated in Table 4.Supp.1.  
The exposure intakes for MMOA chemicals (e.g., chromium) are adjusted for age are calculated in Tables 4.Supp.2.

Abbreviations:  
COPC -- Constituent of potential concern  
CSF -- Oral cancer slope factor  
EPC -- Exposure point concentration  
IUR - Inhalation unit risk  
RfC -- Inhalation reference concentration  
RfD -- Oral or dermal reference dose  
UCL -- Upper confidence limit

Notes:  
The exposure point concentration (EPC) is the 95% upper confidence limit (UCL), except when the UCL was greater than the maximum detected concentration or ProUCL did not calculate an UCL.  
The constituent of potential concern (COPC) list is based on exceedances from screening of maximum detected concentrations against risk-based criteria in the Table 2s.  
The single-chemical cancer risks incorporate the one hit equation if cancer risks are > 0.01, per RAGs Part A Chapter 8: Risk = 1 - exp(-Dose x SF). For the risks presented here, the one-hit equation is not needed.  
The age-adjustments for a resident's cancer risk are calculated in Table 4.Supp.1.  
The exposure intakes for MMOA chemicals (e.g., chromium) are adjusted for age are calculated in Tables 4.Supp.2.

Abbreviations:  
COPC -- Constituent of potential concern  
CSF -- Oral cancer slope factor  
EPC -- Exposure point concentration  
IUR - Inhalation unit risk  
RfC -- Inhalation reference concentration  
RfD -- Oral or dermal reference dose  
UCL -- Upper confidence limit

| Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.              |        |                                                              |        |
| Recommendations are based upon data size, data distribution, and skewness.                                                                |        |                                                              |        |
| These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).                  |        |                                                              |        |
| However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician. |        |                                                              |        |
| result (fluvial_1,1-dichloroethene_75-35-4)                                                                                               |        |                                                              |        |

| Mean (detects)                                                                                                                            | 1.944  |                                                              |        |
| Gamma ROS Statistics using Imputed Non-Detects                                                                                            |        |                                                              |        |
| GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs                                              |        |                                                              |        |
| GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)                 |        |                                                              |        |
| For such situations, GROS method may yield incorrect values of UCLs and BTVs                                                              |        |                                                              |        |
| This is especially true when the sample size is small.                                                                                    |        |                                                              |        |
| For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates                               |        |                                                              |        |

TABLE B.1  
PROUCL 5.1 RAW OUTPUT FOR GROUNDWATER - FLUVIAL AQUIFER  
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

|                                                                                                                                           |        |                                                         |        |
|-------------------------------------------------------------------------------------------------------------------------------------------|--------|---------------------------------------------------------|--------|
| GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs                                              |        |                                                         |        |
| GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)                 |        |                                                         |        |
| For such situations, GROS method may yield incorrect values of UCLs and BTVs                                                              |        |                                                         |        |
| This is especially true when the sample size is small.                                                                                    |        |                                                         |        |
| For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates                               |        |                                                         |        |
| Minimum                                                                                                                                   | 0.01   | Mean                                                    | 0.832  |

| 95% KM Approximate Gamma UCL                                                                                                              | 1.629  |                                                         |        |
| When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test                                            |        |                                                         |        |
| When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL                    |        |                                                         |        |
| Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.              |        |                                                         |        |
| Recommendations are based upon data size, data distribution, and skewness.                                                                |        |                                                         |        |
| These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).                  |        |                                                         |        |
| However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician. |        |                                                         |        |
| result (fluvial_1,2,4-trimethylbenzene_95-63-6)                                                                                           |        |                                                         |        |

| k hat (MLE)                                                                                                                               | 0.63   | k star (bias corrected MLE)                                  | 0.62   |
| Theta hat (MLE)                                                                                                                           | 11.06  | Theta star (bias corrected MLE)                              | 11.24  |
| nu hat (MLE)                                                                                                                              | 153.7  | nu star (bias corrected)                                     | 151.3  |
| Mean (detects)                                                                                                                            | 6.97   |                                                              |        |
| Gamma ROS Statistics using Imputed Non-Detects                                                                                            |        |                                                              |        |
| GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs                                              |        |                                                              |        |
| GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)                 |        |                                                              |        |
| For such situations, GROS method may yield incorrect values of UCLs and BTVs                                                              |        |                                                              |        |
| This is especially true when the sample size is small.                                                                                    |        |                                                              |        |
| For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates                               |        |                                                              |        |
| Minimum                                                                                                                                   | 0.01   | Mean                                                         | 0.758  |

PROUCL 5.1 RAW OUTPUT FOR GROUNDWATER - FLUVIAL AQUIFER  
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

| Gamma Statistics on Detected Data Only                                                                                                    |           |                                                      |        |
|-------------------------------------------------------------------------------------------------------------------------------------------|-----------|------------------------------------------------------|--------|
| k hat (MLE)                                                                                                                               | 0.547     | k star (bias corrected MLE)                          | 0.542  |
| Theta hat (MLE)                                                                                                                           | 32.48     | Theta star (bias corrected MLE)                      | 32.78  |
| nu hat (MLE)                                                                                                                              | 213.2     | nu star (bias corrected)                             | 211.2  |
| Mean (detects)                                                                                                                            | 17.75     |                                                      |        |
| Gamma ROS Statistics using Imputed Non-Detects                                                                                            |           |                                                      |        |
| GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs                                              |           |                                                      |        |
| GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)                 |           |                                                      |        |
| For such situations, GROS method may yield incorrect values of UCLs and BTVs                                                              |           |                                                      |        |
| This is especially true when the sample size is small.                                                                                    |           |                                                      |        |
| For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates                               |           |                                                      |        |
| Minimum                                                                                                                                   | 0.01      | Mean                                                 | 3.059  |
| Maximum                                                                                                                                   | 196       | Median                                               | 0.01   |

| 95% KM Approximate Gamma UCL                                                                                                              | 657    |                                                              |        |
| When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test                                            |        |                                                              |        |
| When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL                    |        |                                                              |        |
| Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.              |        |                                                              |        |
| Recommendations are based upon data size, data distribution, and skewness.                                                                |        |                                                              |        |
| These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).                  |        |                                                              |        |
| However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician. |        |                                                              |        |

| Theta hat (MLE)                                                                                                                           | 11.93  | Theta star (bias corrected MLE)                              | 12     |
| nu hat (MLE)                                                                                                                              | 738.8  | nu star (bias corrected)                                     | 734.7  |
| Mean (detects)                                                                                                                            | 10.78  |                                                              |        |
| Gamma ROS Statistics using Imputed Non-Detects                                                                                            |        |                                                              |        |
| GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs                                              |        |                                                              |        |
| GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)                 |        |                                                              |        |
| For such situations, GROS method may yield incorrect values of UCLs and BTVs                                                              |        |                                                              |        |
| This is especially true when the sample size is small.                                                                                    |        |                                                              |        |
| For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates                               |        |                                                              |        |

| Gamma Statistics on Detected Data Only                                                                                                    |         |                                                              |        |
| k hat (MLE)                                                                                                                               | 0.516   | k star (bias corrected MLE)                                  | 0.499  |
| Theta hat (MLE)                                                                                                                           | 40.44   | Theta star (bias corrected MLE)                              | 41.79  |
| nu hat (MLE)                                                                                                                              | 54.7    | nu star (bias corrected)                                     | 52.94  |
| Mean (detects)                                                                                                                            | 20.87   |                                                              |        |
| Gamma ROS Statistics using Imputed Non-Detects                                                                                            |         |                                                              |        |
| GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs                                              |         |                                                              |        |
| GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)                 |         |                                                              |        |
| For such situations, GROS method may yield incorrect values of UCLs and BTVs                                                              |         |                                                              |        |
| This is especially true when the sample size is small.                                                                                    |         |                                                              |        |
| For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates                               |         |                                                              |        |
| Minimum                                                                                                                                   | 0.01    | Mean                                                         | 0.982  |

HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

|                                                                                                                                           |           |                                                      |        |
|-------------------------------------------------------------------------------------------------------------------------------------------|-----------|------------------------------------------------------|--------|
| Gamma ROS Statistics using Imputed Non-Detects                                                                                            |           |                                                      |        |
| GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs                                              |           |                                                      |        |
| GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)                 |           |                                                      |        |
| For such situations, GROS method may yield incorrect values of UCLs and BTVs                                                              |           |                                                      |        |
| This is especially true when the sample size is small.                                                                                    |           |                                                      |        |
| For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates                               |           |                                                      |        |
| Minimum                                                                                                                                   | 0.01      | Mean                                                 | 2.312  |
| Maximum                                                                                                                                   | 188       | Median                                               | 0.01   |

| Mean (detects)                         | 0.281  |

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

| Suggested UCL to Use                                                                                                                      |           |                                                              |        |
| 95% KM (t) UCL                                                                                                                            | 0.208     |                                                              |        |
| When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test                                            |           |                                                              |        |
| When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL                    |           |                                                              |        |
| Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.              |           |                                                              |        |
| Recommendations are based upon data size, data distribution, and skewness.                                                                |           |                                                              |        |
| These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).                  |           |                                                              |        |
| However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician. |           |                                                              |        |

|                                                                                                                                           |           |                                                      |                          |  |       |
|-------------------------------------------------------------------------------------------------------------------------------------------|-----------|------------------------------------------------------|--------------------------|--|-------|
| nu hat (MLE)                                                                                                                              |           | 198.3                                                | nu star (bias corrected) |  | 195.2 |
| Mean (detects)                                                                                                                            |           | 2.387                                                |                          |  |       |
| Gamma ROS Statistics using Imputed Non-Detects                                                                                            |           |                                                      |                          |  |       |
| GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs                                              |           |                                                      |                          |  |       |
| GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)                 |           |                                                      |                          |  |       |
| For such situations, GROS method may yield incorrect values of UCLs and BTVs                                                              |           |                                                      |                          |  |       |
| This is especially true when the sample size is small.                                                                                    |           |                                                      |                          |  |       |
| For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates                               |           |                                                      |                          |  |       |
| Minimum                                                                                                                                   | 0.01      | Mean                                                 | 1.326                    |  |       |

| Mean (detects)                                                                                                                            | 4.325     |                                                              |        |
| Gamma ROS Statistics using Imputed Non-Detects                                                                                            |           |                                                              |        |
| GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs                                              |           |                                                              |        |
| GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)                 |           |                                                              |        |
| For such situations, GROS method may yield incorrect values of UCLs and BTVs                                                              |           |                                                              |        |
| This is especially true when the sample size is small.                                                                                    |           |                                                              |        |
| For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates                               |           |                                                              |        |
| Minimum                                                                                                                                   | 0.01      | Mean                                                         | 2.134  |

|-------------------------------------------------------------------------------------------------------------------------------------------|--------|------------------------------------------------------|--------|
| k hat (MLE)                                                                                                                               | 1.707  | k star (bias corrected MLE)                          | 1.505  |
| Theta hat (MLE)                                                                                                                           | 0.889  | Theta star (bias corrected MLE)                      | 1.008  |
| nu hat (MLE)                                                                                                                              | 75.13  | nu star (bias corrected)                             | 66.22  |
| Mean (detects)                                                                                                                            | 1.517  |                                                      |        |
| Gamma ROS Statistics using Imputed Non-Detects                                                                                            |        |                                                      |        |
| GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs                                              |        |                                                      |        |
| GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)                 |        |                                                      |        |
| For such situations, GROS method may yield incorrect values of UCLs and BTVs                                                              |        |                                                      |        |
| This is especially true when the sample size is small.                                                                                    |        |                                                      |        |
| For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates                               |        |                                                      |        |
| Minimum                                                                                                                                   | 0.01   | Mean                                                 | 0.146  |

| Mean (detects)                                                                                                            | 0.691   |                                                                 |        |
| Gamma ROS Statistics using Imputed Non-Detects                                                                            |         |                                                                 |        |
| GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs                              |         |                                                                 |        |
| GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20) |         |                                                                 |        |
| For such situations, GROS method may yield incorrect values of UCLs and BTVs                                              |         |                                                                 |        |
| This is especially true when the sample size is small.                                                                    |         |                                                                 |        |
| For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates               |         |                                                                 |        |
| Minimum                                                                                                                   | 0.0478  | Mean                                                            | 0.534  |

| Mean (detects)                                                                                                                            | 0.205   |                                                                 |        |
| Gamma ROS Statistics using Imputed Non-Detects                                                                                            |         |                                                                 |        |
| GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs                                              |         |                                                                 |        |
| GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)                 |         |                                                                 |        |
| For such situations, GROS method may yield incorrect values of UCLs and BTVs                                                              |         |                                                                 |        |
| This is especially true when the sample size is small.                                                                                    |         |                                                                 |        |
| For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates                               |         |                                                                 |        |
| Minimum                                                                                                                                   | 0.0709  | Mean                                                            | 0.178  |

TABLE B.3  
PROUCL 5.1 RAW OUTPUT FOR GROUNDWATER - MEMPHIS AQUIFER  
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

|                                                                                                                                           |        |                                                         |         |
|-------------------------------------------------------------------------------------------------------------------------------------------|--------|---------------------------------------------------------|---------|
| Gamma ROS Statistics using Imputed Non-Detects                                                                                            |        |                                                         |         |
| GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs                                              |        |                                                         |         |
| GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)                 |        |                                                         |         |
| For such situations, GROS method may yield incorrect values of UCLs and BTVs                                                              |        |                                                         |         |
| This is especially true when the sample size is small.                                                                                    |        |                                                         |         |
| For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates                               |        |                                                         |         |
| Minimum                                                                                                                                   | 0.01   | Mean                                                    | 1.91    |
| Maximum                                                                                                                                   | 10.9   | Median                                                  | 0.901   |

| Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.              |        |                                                                 |       |
| Recommendations are based upon data size, data distribution, and skewness.                                                                |        |                                                                 |       |
| These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).                  |        |                                                                 |       |
| However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician. |        |                                                                 |       |

TABLE B.4  
PROJUL 5.1 RAW INPUT FOR GROUNDWATER  
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

**Notes:**  
The data set provided here are for constituents of potential concern (COPCs) that were determined in the initial screening to calculate 95% upper confidence limits (UCLs) using USEPA PROJUL software for the risk assessment. This is not a complete data set.  
The maximum of the field duplicate and parent sample results was applied.  
The detection limit is the method detection limit if available; otherwise, it is the reporting limit.

TABLE B.4  
PROJUL.S.1 RAW INPUT FOR GROUNDWATER  
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

**Notes:**  
The data set provided here are for constituents of potential concern (COPCs) that were determined in the initial screening to calculate 95% upper confidence limits (UCLs) using USEPA PROJUL software for the risk assessment. This is not a complete data set.  
The maximum of the field duplicate and parent sample results was applied.  
The detection limit is the method detection limit if available; otherwise, it is the reporting limit.

TABLE B.4  
PROJULS 1 RAW INPUT FOR GROUNDWATER  
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

**Notes:**  
The data set provided here are for constituents of potential concern (COPCs) that were determined in the initial screening to calculate 95% upper confidence limits (UCLs) using USEPA PROJUL software for the risk assessment. This is not a complete data set.  
The maximum of the field duplicate and parent sample results was applied.  
The detection limit is the method detection limit if available; otherwise, it is the reporting limit.

TABLE B.4  
PROJUL 5.1 RAW INPUT FOR GROUNDWATER  
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

**Notes:**  
The data set provided here are for constituents of potential concern (COPCs) that were determined in the initial screening to calculate 95% upper confidence limits (UCLs) using USEPA PROJUL software for the risk assessment. This is not a complete data set.  
The maximum of the field duplicate and parent sample results was applied.  
The detection limit is the method detection limit if available; otherwise, it is the reporting limit.

TABLE B-4  
PROJUL 5.1 RAW INPUT FOR GROUNDWATER  
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

**Notes:**  
The data set provided here are for constituents of potential concern (COPCs) that were determined in the initial screening to calculate 95% upper confidence limits (UCLs) using USEPA PROJUL software for the risk assessment. This is not a complete data set.  
The maximum of the field duplicate and parent sample results was applied.  
The detection limit is the method detection limit if available; otherwise, it is the reporting limit.

TABLE B.4  
PROJUL161 RAW INPUT FOR GROUNDWATER  
HUMAN-HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

**Notes:**  
The data set provided here are for constituents of potential concern (COPCs) that were determined in the initial screening to calculate 95% upper confidence limits (UCLs) using USEPA ProUCL software for the risk assessment. This is not a complete data set.  
The maximum of the field duplicate and parent sample results was applied.  
The detection limit is the method detection limit if available; otherwise, it is the reporting limit.

| ProUCL Group                             | ProUCL Result (ug/L) | ProUCL Flag | Location  | Sample ID                         | Sample Date | Analysis Date | Analytical Method   | T or D | COPC Group | COPC                      | CASRN   | Qualifier | Detection Limit (ug/L) |

TABLE B.4  
PROJCL 5.1 RAW INPUT FOR GROUNDWATER  
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

Notes:  
The data set provided here are for constituents of potential concern (COPCs) that were determined in the initial screening to calculate 95% upper confidence limits (UCLs) using USEPA PROJCL software for the risk assessment. This is not a complete data set.  
The maximum of the field duplicate and parent sample results was applied.  
The detection limit is the method detection limit if available; otherwise, it is the reporting limit.

TABLE B.4  
PROJCL 5.1 RAW INPUT FOR GROUNDWATER  
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

Notes:  
The data set provided here are for constituents of potential concern (COPCs) that were determined in the initial screening to calculate 95% upper confidence limits (UCLs) using USEPA ProUCL software for the risk assessment. This is not a complete data set.  
The maximum of the field duplicate and parent sample results was applied.  
The detection limit is the method detection limit if available; otherwise, it is the reporting limit.

TABLE B.4  
PROJCL 1 RAW INPUT FOR GROUNDWATER  
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

**Notes:**  
The data set provided here are for constituents of potential concern (COPCs) that were determined in the initial screening to calculate 95% upper confidence limits (UCLs) using USEPA PROJCL software for the risk assessment. This is not a complete data set.  
The maximum of the field duplicate and parent sample results was applied.  
The detection limit is the method detection limit if available; otherwise, it is the reporting limit.

TABLE B-4  
PROCL 5.1 RAW INPUT FOR GROUNDWATER  
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

**Notes:**  
The data set provided here are for constituents of potential concern (COPCs) that were determined in the initial screening to calculate 95% upper confidence limits (UCLs) using USEPA ProUCL software for the risk assessment. This is not a complete data set.  
The maximum of the field duplicate and parent sample results was applied.  
The detection limit is the method detection limit if available; otherwise, it is the reporting limit.

| ProUCL Group                       | ProUCL Result (ug/L) | ProUCL Flag | Location  | Sample ID                             | Sample Date | Analysis Date | Analytical Method    | T or D | COPC Group | COPC               | CASRN   | Qualifier | Detection Limit (ug/L) |

TABLE B.4  
PROJCL 5.1 RAW INPUT FOR GROUNDWATER  
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

**Notes:**  
The data set provided here are for constituents of potential concern (COPCs) that were determined in the initial screening to calculate 95% upper confidence limits (UCLs) using USEPA PROJCL software for the risk assessment. This is not a complete data set.  
The maximum of the field duplicate and parent sample results was applied.  
The detection limit is the method detection limit if available; otherwise, it is the reporting limit.

TABLE B.4  
PROJUL 5.1 RAW INPUT FOR GROUNDWATER  
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

**Notes:**  
The data set provided here are for constituents of potential concern (COPCs) that were determined in the initial screening to calculate 95% upper confidence limits (UCLs) using USEPA PROJUL software for the risk assessment. This is not a complete data set.  
The maximum of the field duplicate and parent sample results was applied.  
The detection limit is the method detection limit if available; otherwise, it is the reporting limit.

TABLE B.4  
PROJUL 5.1 RAW INPUT FOR GROUNDWATER  
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

**Notes:**  
The data set provided here are for constituents of potential concern (COPCs) that were determined in the initial screening to calculate 95% upper confidence limits (UCLs) using USEPA PROJUL software for the risk assessment. This is not a complete data set.  
The maximum of the field duplicate and parent sample results was applied.  
The detection limit is the method detection limit if available; otherwise, it is the reporting limit.

TABLE B.4  
PROJCL 5.1 RAW INPUT FOR GROUNDWATER  
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

**Notes:**  
The data set provided here are for constituents of potential concern (COPCs) that were determined in the initial screening to calculate 95% upper confidence limits (UCLs) using USEPA PROJCL software for the risk assessment. This is not a complete data set.  
The maximum of the field duplicate and parent sample results was applied.  
The detection limit is the method detection limit if available; otherwise, it is the reporting limit.

| ProUCL Group                              | ProUCL Result (ug/L) | ProUCL Flag | Location   | Sample ID                               | Sample Date | Analysis Date | Analytical Method   | T or D | COPC Group | COPC                   | CASRN   | Qualifier | Detection Limit (ug/L) |

TABLE B.4  
PROJCL 5.1 RAW INPUT FOR GROUNDWATER  
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

**Notes:**  
The data set provided here are for constituents of potential concern (COPCs) that were determined in the initial screening to calculate 95% upper confidence limits (UCLs) using USEPA PROJCL software for the risk assessment. This is not a complete data set.  
The maximum of the field duplicate and parent sample results was applied.  
The detection limit is the method detection limit if available; otherwise, it is the reporting limit.

TABLE B.4  
PROJUL 5.1 RAW INPUT FOR GROUNDWATER  
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

**Notes:**  
The data set provided here are for constituents of potential concern (COPCs) that were determined in the initial screening to calculate 95% upper confidence limits (UCLs) using USEPA PROJUL software for the risk assessment. This is not a complete data set.  
The maximum of the field duplicate and parent sample results was applied.  
The detection limit is the method detection limit if available; otherwise, it is the reporting limit.

| ProUCL Group                          | ProUCL Result (ug/L) | ProUCL Flag | Location | Sample ID                           | Sample Date | Analysis Date | Analytical Method  | T or D | COPC Group | COPC                   | CASRN   | Qualifier | Detection Limit (ug/L) |
|---------------------------------------|----------------------|-------------|----------|-------------------------------------|-------------|---------------|--------------------|--------|------------|------------------------|---------|-----------|------------------------|

TABLE B.4  
PROJCL.5.1 RAW INPUT FOR GROUNDWATER  
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

Notes:  
The data set provided here are for constituents of potential concern (COPCs) that were determined in the initial screening to calculate 95% upper confidence limits (UCLs) using USEPA PROJCL software for the risk assessment. This is not a complete data set.  
The maximum of the field duplicate and parent sample results was applied.  
The detection limit is the method detection limit if available; otherwise, it is the reporting limit.

| ProUCL Group                           | ProUCL Result (ug/L) | ProUCL Flag | Location | Sample ID                         | Sample Date | Analysis Date | Analytical Method    | T or D | COPC Group | COPC                   | CASRN   | Qualifier | Detection Limit (ug/L) |

TABLE B.4  
PROJUL.S.1 RAW INPUT FOR GROUNDWATER  
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

**Notes:**  
The data set provided here are for constituents of potential concern (COPCs) that were determined in the initial screening to calculate 95% upper confidence limits (UCLs) using USEPA ProUCL software for the risk assessment. This is not a complete data set.  
The maximum of the field duplicate and parent sample results was applied.  
The detection limit is the method detection limit if available; otherwise, it is the reporting limit.

| ProUCL Group                            | ProUCL Result (ug/L) | ProUCL Flag | Location | Sample ID                       | Sample Date | Analysis Date | Analytical Method | T or D | COPC Group | COPC                   | CASRN   | Qualifier | Detection Limit (ug/L) |

TABLE B.4  
PROJCL 5.1 RAW INPUT FOR GROUNDWATER  
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

**Notes:**  
The data set provided here are for constituents of potential concern (COPCs) that were determined in the initial screening to calculate 95% upper confidence limits (UCLs) using USEPA PROJCL software for the risk assessment. This is not a complete data set.  
The maximum of the field duplicate and parent sample results was applied.  
The detection limit is the method detection limit if available; otherwise, it is the reporting limit.

| ProUCL Group                            | ProUCL Result (ug/L) | ProUCL Flag | Location    | Sample ID                                | Sample Date | Analysis Date | Analytical Method   | T or D | COPC Group | COPC                   | CASRN   | Qualifier | Detection Limit (ug/L) |

TABLE B.4  
PROJCL 5.1 RAW INPUT FOR GROUNDWATER  
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

**Notes:**  
The data set provided here are for constituents of potential concern (COPCs) that were determined in the initial screening to calculate 95% upper confidence limits (UCLs) using USEPA PROJCL software for the risk assessment. This is not a complete data set.  
The maximum of the field duplicate and parent sample results was applied.  
The detection limit is the method detection limit if available; otherwise, it is the reporting limit.

| ProUCL Group                            | ProUCL Result (ug/L) | ProUCL Flag | Location   | Sample ID                               | Sample Date | Analysis Date | Analytical Method    | T or D | COPC Group | COPC                   | CASRN   | Qualifier | Detection Limit (ug/L) |

TABLE B.4  
PROJCL 5.1 RAW INPUT FOR GROUNDWATER  
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

**Notes:**  
The data set provided here are for constituents of potential concern (COPCs) that were determined in the initial screening to calculate 95% upper confidence limits (UCLs) using USEPA PROJCL software for the risk assessment. This is not a complete data set.  
The maximum of the field duplicate and parent sample results was sampled.  
The detection limit is the method detection limit if available; otherwise, it is the reporting limit.

| ProUCL Group                          | ProUCL Result (ug/L) | ProUCL Flag | Location | Sample ID                           | Sample Date | Analysis Date | Analytical Method | T or D | COPC Group | COPC                   | CASRN   | Qualifier | Detection Limit (ug/L) |

TABLE B.4  
PROJCL 5.1 RAW INPUT FOR GROUNDWATER  
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

**Notes:**  
The data set provided here are for constituents of potential concern (COPCs) that were determined in the initial screening to calculate 95% upper confidence limits (UCLs) using USEPA PROJCL software for the risk assessment. This is not a complete data set.  
The maximum of the field duplicate and parent sample results was applied.  
The detection limit is the method detection limit if available; otherwise, it is the reporting limit.

| ProUCL Group                       | ProUCL Result (ug/L) | ProUCL Flag | Location | Sample ID                         | Sample Date | Analysis Date | Analytical Method    | T or D | COPC Group | COPC               | CASRN    | Qualifier | Detection Limit (ug/L) |

TABLE B.4  
PROJUL S.1 RAW INPUT FOR GROUNDWATER  
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

**Notes:**  
The data set provided here are for constituents of potential concern (COPCs) that were determined in the initial screening to calculate 95% upper confidence limits (UCLs) using USEPA ProUCL software for the risk assessment. This is not a complete data set.  
The maximum of the field duplicate and parent sample results was applied.  
The detection limit is the method detection limit if available; otherwise, it is the reporting limit.

| ProUCL Group                        | ProUCL Result (µg/L) | ProUCL Flag | Location | Sample ID                      | Sample Date | Analysis Date | Analytical Method    | T or D | COPC Group | COPC               | CASRN    | Qualifier | Detection Limit (µg/L) |

TABLE B.4  
PROJCL S.1 RAW INPUT FOR GROUNDWATER  
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

**Notes:**  
The data set provided here are for constituents of potential concern (COPCs) that were determined in the initial screening to calculate 95% upper confidence limits (UCLs) using USEPA PROJCL software for the risk assessment. This is not a complete data set.  
The maximum of the field duplicate and parent sample results was applied.  
The detection limit is the method detection limit if available; otherwise, it is the reporting limit.

| ProUCL Group                       | ProUCL Result (µg/L) | ProUCL Flag | Location | Sample ID                        | Sample Date | Analysis Date | Analytical Method    | T or D | COPC Group | COPC               | CASRN    | Qualifier | Detection Limit (µg/L) |

TABLE B.4  
PROJCL S.1 RAW INPUT FOR GROUNDWATER  
HAZARDOUS AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

**Notes:**  
The data set provided here are for constituents of potential concern (COPCs) that were determined in the initial screening to calculate 95% upper confidence limits (UCLs) using USEPA PROJCL software for the risk assessment. This is not a complete data set.  
The maximum of the field duplicate and parent sample results was applied.  
The detection limit is the method detection limit if available; otherwise, it is the reporting limit.

TABLE B.4  
PROJCL 5.1 RAW INPUT FOR GROUNDWATER  
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

**Notes:**  
The data set provided here are for constituents of potential concern (COPCs) that were determined in the initial screening to calculate 95% upper confidence limits (UCLs) using USEPA ProUCL software for the risk assessment. This is not a complete data set.  
The maximum of the field duplicate and parent sample results was applied.  
The detection limit is the method detection limit if available; otherwise, it is the reporting limit.

TABLE B.4  
PROJCL 5.1 RAW INPUT FOR GROUNDWATER  
HUMAN-HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPT MEMPHIS, TENNESSEE

**Notes:**  
The data set provided here are for constituents of potential concern (COPCs) that were determined in the initial screening to calculate 95% upper confidence limits (UCLs) using USEPA ProJCL software for the risk assessment. This is not a complete data set.  
The maximum of the field duplicate and parent sample results was applied.  
The detection limit is the method detection limit if available; otherwise, it is the reporting limit.

TABLE B.4  
PROJCL 5.1 RAW INPUT FOR GROUNDWATER  
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

**Notes:**  
The data set provided here are for constituents of potential concern (COPCs) that were determined in the initial screening to calculate 95% upper confidence limits (UCLs) using USEPA PROJCL software for the risk assessment. This is not a complete data set.  
The maximum of the field duplicate and parent sample results was applied.  
The detection limit is the method detection limit if available; otherwise, it is the reporting limit.

| ProUCL Group                       | ProUCL Result (µg/L) | ProUCL Flag | Location | Sample ID                       | Sample Date | Analysis Date | Analytical Method   | T or D | COPC Group | COPC                | CASRN   | Qualifier | Detection Limit (µg/L) |

TABLE B.4  
PROJUL.S.1 RAW INPUT FOR GROUNDWATER  
HUMAN-HEALTH AND ECOLOGICAL RISK ASSESSMENT  
MAIN INSTALLATION - DEFENSE DEPOT MEMPHIS, TENNESSEE

**Notes:**  
The data set provided here are for constituents of potential concern (COPCs) that were determined in the initial screening to calculate 95% upper confidence limits (UCLs) using USEPA ProUCL software for the risk assessment. This is not a complete data set.  
The maximum of the field duplicate and parent sample results was applied.  
The detection limit is the method detection limit if available; otherwise, it is the reporting limit.

| ProUCL Group                       | ProUCL Result (µg/L) | ProUCL Flag | Location | Sample ID                       | Sample Date | Analysis Date | Analytical Method    | T or D | COPC Group | COPC                | CASRN   | Qualifier | Detection Limit (µg/L) |
